ABSTRACT

Background

Crohn's disease (CD) is a chronic relapsing inflammatory condition and maintenance of remission is a major issue as many patients fail to achieve remission with medical management and require surgical interventions. Purine analogues such as azathioprine (AZA) and 6-mercaptopurine (6-MP) have been used to maintain surgically-induced remission in CD, but the effectiveness, tolerability and safety of these agents remains controversial.

Objectives

To assess the efficacy and safety of purine analogues (AZA and 6-MP) for maintenance of surgically-induced remission in CD.

Search methods

We searched PubMed, MEDLINE, Embase, CENTRAL, and the Cochrane IBD Group Specialized Register from inception to 26 July 2018 (and from inception to 31 July 2019). In addition, we searched reference lists of all included studies and relevant reviews, conference proceedings and trials registers.

Selection criteria

Randomised controlled trials (RCTs) with a duration of at least three months that enrolled adults and children with surgically-induced remission of CD and compared AZA or 6-MP to no treatment, placebo or any other active intervention were considered for inclusion.

Data collection and analysis

Two authors independently assessed trial eligibility, extracted data, assessed the risk of bias and assessed the certainty of the evidence using GRADE. The primary outcome was clinical relapse. Secondary outcomes included endoscopic relapse, radiologic and surgical relapse, adverse events (AEs), serious adverse events (SAEs), withdrawal due to AEs and health-related quality of life.

Main results

Ten RCTs with a total of 928 participants were included. Study participants were adults recruited from university clinics and gastroenterology hospitals who received interventions post-surgery for a duration between 12 to 36 months. Most study participants were recruited less than three months after surgery in all except one study where participants were recruited between 6 to 24 months post-surgery. One study was rated as low risk of bias, six studies were rated high risk of bias and three were rated unclear risk of bias.

1

There was moderate certainty evidence that purine analogues are more efficient for preventing clinical relapse than placebo. At 12 to 36 months, 51% (109/215) of AZA/6-MP participants relapsed compared to 64% (124/193) of placebo participants (RR 0.79; 95% CI 0.67 to 0.92; 408 participants; 3 studies; $I^2 = 0\%$; moderate certainty evidence). The certainty of the evidence regarding the efficacy of AZA or 6-MP for maintaining postoperative clinical remission compared to 5-ASA compounds was low. At 12 to 24 months, 64% (113/177) of purine analogue participants relapsed compared to 59% (101/170) of 5-ASA participants (RR 1.05; 95% CI 0.89 to 1.24; 347 participants; 4 studies; $I^2 = 8\%$; low certainty evidence). The certainty of evidence that purine analogues are inferior for preventing postsurgical clinical relapse compared to tumour necrosis factor alpha agents (anti-TNF- α) was very low. At 12 to 24 months, 43% (29/67) of AZA participants relapsed compared to 14% (10/72) of anti-TNF- α participants (RR 2.89; 95% CI 1.50 to 5.57; 139 participants; 3 studies; $I^2 = 0\%$; very low certainty evidence).

The effect of purine analogues compounds on AEs compared to placebo or any active treatment was uncertain, as the quality of evidence ranged from very low to low. After 12 to 24 months, 14% (12/87) of purine analogue participants experienced an AE compared to 10% (8/81) of placebo participants (RR 1.36; 95% CI 0.57 to 3.27; 168 participants; 2 studies; $I^2 = 0\%$; low certainty evidence). The effect of purine analogues on AEs compared to 5-ASA agents was uncertain. After 12 to 24 months, 41% (73/176) of purine analogue participants had an AE compared to 47% (81/171) of 5-ASA participants (RR 0.89; 95% CI 0.74 to 1.07; 346 participants; 4 studies; $I^2 = 15\%$; low certainty evidence). The effect of purine analogues on AEs in comparison to anti TNF- α agents was uncertain. At 12 to 24 months, 57% (32/56) of AZA participants had an AE compared to 51% (31/61) of anti-TNF- α participants (RR 1.13; 95% CI 0.83 to 1.53; 117 participants; 2 studies; $I^2 = 0\%$; low certainty evidence). Purine analogue participants were more like than 5-ASA participants to have a SAE (RR 3.39, 95% CI 1.26 to 9.13, 311 participants; 3 studies; $I^2 = 9\%$; very low certainty evidence), or to withdraw due to an AE (RR 2.21, 95% CI 1.28 to 3.81; 425 participants; 5 studies; $I^2 = 0\%$; low certainty evidence). Commonly reported AEs across all studies included leucopenia, arthralgia, abdominal pain or severe epigastric intolerance, elevated liver enzymes, nausea and vomiting, pancreatitis, anaemia, nasopharyngitis and flatulence.

Authors' conclusions

Moderate certainty evidence suggests that AZA and 6-MP may be superior to placebo for maintenance of surgically-induced remission in participants with CD. There was no clear difference in the number of clinical relapses when purine analogues were compared with 5-ASA agents, however this is based on low certainty evidence. There was very low certainty evidence that AZA and 6-MP are more likely to result in more serious adverse events (SAEs) and withdrawals due to an AE (low certainty) when compared to 5-ASA agents. Very low certainty evidence suggests that purine analogues may be inferior to anti-TNF- α agents, however, no firm conclusions can be drawn. Further research investigating the efficacy and safety of AZA and 6-MP in comparison to other active medications in surgically-induced remission of CD is warranted.

PLAIN LANGUAGE SUMMARY

Azathioprine and 6-mercaptopurine for the maintenance of surgically-induced remission in Crohn's disease

What was the aim of this review?

The aim of this review was to understand the benefits and harms of purine analogues (azathioprine (AZA) and 6-mercaptopurine (6-MP)) used for maintaining remission following surgery in people with Crohn's disease (CD).

What is Crohn's disease?

Crohn's disease is a chronic disease of the gut. The disease is known to constantly change from periods when sufferers have symptoms (relapse) to periods when the symptoms disappear (remission) for a short time. Symptoms include abdominal pain, diarrhoea and weight loss. People with Crohn's disease may undergo surgery to remove diseased parts of their gut. However, their symptoms can return after a short time. Different drugs can be given to ensure that people with Crohn's disease are free from symptoms for as long as possible. However, there are concerns about possible side effects that may arise. Purine analogues (AZA and 6-MP) are a group of immunosuppressive drugs which have been used for over five decades to manage Crohn's disease. We researched whether purine antimetabolites can maintain remission in people with Crohn's disease after the diseased portion of their gut has been removed.

What are the main results of the review?

The review authors found 10 relevant studies with a total of 928 participants, conducted across several European countries, Israel and the US. The studies included people with Crohn's disease over 16 years of age who had undergone surgery and were free from

symptoms. These studies compared purine analogues with placebo (e.g. a sugar pill), or oral 5-aminosalicylic acid (5-ASA) formulations or with anti-tumour necrosis factor-alpha (anti-TNF- α) drugs. 5-ASA and anti-TNF- α drugs are used to reduce inflammation (pain and swelling) in the gut.

One study was high quality, while six studies were of lower quality and three studies did not report enough information to make a judgement on quality. Purine analogues are probably better than placebo for maintaining surgically-induced remission of Crohn's disease (moderate certainty evidence). The analysis of studies that compared purine antimetabolites to 5-ASA medications found no difference in the number of people who remained in remission. However, more people who received purine analogues experienced serious side effects or discontinued treatment due to side effects than those who received 5-ASA (very low and low certainty evidence). The analysis of studies that compared purine analogues to anti-TNF- α drugs showed that purine analogues were less effective for maintaining remission of Crohn's disease after surgery. However, the overall certainty of evidence was very low. Well designed studies

are needed to better understand the benefits and harms of purine analogues compared with anti-TNF- α agents and other active drugs used for Crohn's disease. Due to sparse data and inconsistent reporting across all studies, the effect of purine analogues on side effects compared with placebo, 5-ASA or biologics was uncertain. Commonly reported side effects across the studies included leucopenia (a reduction in the number of white cells in the blood), pancreatitis (inflamed pancreas), arthralgia (joint pain), abdominal pain or severe epigastric intolerance, elevated liver enzymes, nausea and vomiting, anaemia (low number of red blood cells), nasopharyngitis (common cold) and flatulence (intestinal gas).

How up-to-date is this review?

The review authors searched for studies that had been published up to 31 July 2019.

Conclusions

There is moderate certainty evidence that AZA and 6-MP may be superior to placebo for maintenance of surgically-induced remission in participants with Crohn's disease. There was no clear difference in the number of clinical relapses when purine analogues were compared with 5-ASA agents, however this was based on low certainty evidence. There was very low certainty evidence that AZA and 6-MP are more likely to result in more serious side effects and withdrawals due to side effects when compared to 5-ASA agents. Very low certainty evidence suggests that purine analogues may be inferior to anti-TNF- α agents for preventing relapse, however, no firm conclusions can be drawn. Further research investigating the benefits and harms of AZA and 6-MP in comparison to other active medications in surgically-induced remission of CD is warranted.

SUMMARY OF FINDINGS FOR THE MAIN COMPARISON *[Explanation]*

Azathioprine or 6-mercaptopurine compared to placebo for maintenance of surgically-induced remission in Crohn's disease						
Patient or population: People with surgically-induced remission in Crohn's disease Setting: Outpatient Intervention: Azathioprine (100-150 mg/day) or 6-mercaptopurine (1 mg/kg/day - 50 mg/day) Comparison: Placebo						
Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	No of participants (studies)	Certainty of the evidence (GRADE)	Comments
	Risk with placebo	Risk with Azathioprine or 6-mercaptopurine				
Clinical relapse Follow-up: 12 to 36 months	Study population		RR 0.79 (0.67 to 0.92)	408 (3 RCTs)	⊕⊕⊕○ MODERATE ¹	Clinical relapse defined as: a CDAI>250 (D'Haens 2008); a CDAI>150 and 100 point increase from baseline (Mowat 2016) or a grading score > 2 (Hanauer 2004).
	642 per 1,000	508 per 1,000 (430 to 591)				
Endoscopic relapse Follow-up:12 to 36 months	Study population		RR 0.85 (0.64 to 1.13)	321 (2 RCTs)	⊕⊕○○ LOW ²³	Endoscopic relapse defined as an endoscopic score i ≥2 (D'Haens 2008; Mowat 2016)
	752 per 1,000	639 per 1,000 (481 to 849)				
Radiologic relapse	Outcome not reported					Not reported
Surgical relapse	Outcome not reported					Not reported
Adverse events Follow-up: 12 to 24 months	Study population		RR 1.36 (0.57 to 3.27)	168 (2 RCTs)	⊕⊕○○ LOW ⁴	Reported adverse events include hair loss, leukopenia, diarrhoea, abdominal pain, hepatotoxicity and arthralgia

	99 per 1,000	134 per 1,000 (56 to 323)				
Serious adverse events Follow-up: 12 to 36 months	Study population		RR 1.78 (0.39 to 8.18)	327 (2 RCTs)	⊕⊕○○ LOW ⁵	Reported serious adverse events include arthralgia, pancreatitis, leucopenia and bowel obstruction
	13 per 1,000	23 per 1,000 (5 to 108)				
Withdrawal due to adverse events Follow-up: 12 to 36 months	Study population		RR 0.90 (0.63 to 1.29)	408 (3 RCTs)	⊕⊕⊕○ MODERATE ⁶	Adverse events leading to withdrawal included abnormal blood results leading to temporary discontinuation of treatment in 28% of the participants. However, specific details on reasons for discontinuation were not clearly stated
	254 per 1,000	228 per 1,000 (160 to 328)				

* **The risk in the intervention group** (and its 95% confidence interval) is based on the median risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; RR: Risk ratio; OR: Odds ratio;

GRADE Working Group grades of evidence

High certainty: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate certainty: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low certainty: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low certainty: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

¹ Downgraded one level due serious imprecision (233 events).

² Downgraded one level due to serious inconsistency ($I^2 = 64\%$).

³ Downgraded one level due to serious imprecision (227 events).

⁴ Downgraded two levels due to very serious imprecision (20 events) and 95% CI which includes appreciable benefit and harm

⁵ Downgraded two levels due to very serious imprecision (7 events) and 95% CI which includes appreciable benefit and harm

⁶ Downgraded one level due to serious imprecision (100 events) and 95% CI which includes appreciable benefit and harm

BACKGROUND

Description of the condition

Crohn's disease is a chronic idiopathic inflammatory disorder of the gastrointestinal tract with an etiology that combines genetic predisposition, environmental factors and an inappropriate immune response to the gut microbiota which may involve the whole gastrointestinal tract (Abraham 2009). There is no cure for the disease, and management strategies are mainly focused on induction and maintenance of remission. Approximately 75% of patients with Crohn's disease will eventually undergo surgical resection (Bernell 2000), and this can induce remission. However, endoscopic recurrence of disease has been reported to be as high as 73% at one year post surgery (Rutgeerts 1990), and clinical relapse rates have been reported to range from 22 to 55% at five years post surgery (Williams 1990). There is no standard therapy for the prevention of postoperative recurrence in Crohn's disease (Hanauer 2001). A number of agents have been studied, but considerable uncertainty remains as to the efficacy of such treatments.

Description of the intervention

Corticosteroids, the mainstay of treatment of acute exacerbations, have been used extensively as Crohn's disease therapy. However, the chronic use of glucocorticosteroids is limited due to the multiple adverse reactions and the lack of effectiveness for maintaining remission in Crohn's disease (Steinhart 2003). 5-aminosalicylic acid (5-ASA) agents have been shown to be safe and may be effective for maintenance of post-surgical remission, although the existing data suggests that the efficacy of these agents depends on the ability of these drugs to reach the terminal ileum and colon in therapeutic concentrations and may have limited clinical efficacy (Gordon 2011). Probiotics and budesonide do not appear to provide any benefit for maintenance of surgically-induced remission in Crohn's disease (Benchimol 2009; Doherty 2009; Rolfe 2006). Nitroimidazole antibiotics may reduce the risk of relapse in surgically-induced remission, however, these agents are not well tolerated and are associated with a higher risk of serious adverse events (Doherty 2009). Studies have demonstrated that tumour necrosis factor- α (TNF- α) antagonists such as infliximab (Regueiro 2009), or adalimumab (Savarino 2013) may provide a benefit for reducing the risk of relapse in surgically-induced remission, but these agents are expensive. Purine analogues such as azathioprine (AZA) and 6-mercaptopurine (6-MP) have been used in clinical practice for over five decades with a demonstrated efficacy for the long-term maintenance of remission in both Crohn's disease (Chande 2015), and ulcerative colitis (Timmer 2016), and are relatively inexpensive. Evidence suggests that the effect of thiopurine formulations seem to last for up to five years (Fraser 2002), significantly reducing the risk of perianal and intestinal surgery (Camus 2013).

How the intervention might work

6-MP and its prodrug AZA which is non-enzymatically degraded to 6-MP are purine antimetabolites that reduce cell proliferation and have immune modulating properties. 6-MP is metabolised to its active component 6-thioguanine nucleotide which competitively interferes with nucleic acid metabolism by inhibiting the proliferation of T and B lymphocytes and reducing the numbers of cytotoxic T cells and plasma cells (Lennard 1992; Sahasranaman 2008). There are some trial data which suggest that neutrophil count is a predictor of induction and maintenance of remission (Colonna 1994), which may suggest the mechanism of action, although this is not well understood. The major limiting factor for long term use of AZA and 6-MP agents has been the occurrence of adverse events in approximately 10% of patients leading to withdrawal of therapy (Hafraoui 2002), with dose-dependent and idiosyncratic adverse events occurring. There is evidence which suggests that thiopurine methyltransferase deficiency accounts for some of the dose and metabolism-related toxicity to purine analogues including leucopenia, thrombocytopenia and in the long-term potentially lymphoma and non-melanoma skin cancer (Axelrad 2016; Gomollon 2017; Lennard 1989; Weinsilboum 1980), while adverse reactions such as arthralgias, pancreatitis, hepatitis, nausea, non-pancreatic abdominal pain, rash, fever and diarrhoea are attributed to hypersensitivity reactions (Sandborn 1996).

Why it is important to do this review

Maintenance of remission in Crohn's disease is a major issue as many patients fail to achieve remission with medical management and require surgical interventions. Purine analogues have been used to maintain surgically-induced remission in Crohn's disease, but the effectiveness, tolerability and safety of these drugs remains controversial. Relatively few studies have been published that investigate the role of AZA or 6-MP for maintenance of remission following surgery in patients with Crohn's disease. One multicentre randomised placebo controlled trial involving 81 patients found a significant reduction in endoscopic recurrence when AZA was used in conjunction with metronidazole in comparison to metronidazole alone (D'Haens 2008). In another multicentre randomised controlled trial, it was concluded that 6-mercaptopurine was more effective than either mesalamine or placebo at preventing postoperative recurrence at 24 months following surgery (Hanauer 2001). However, a single-centre randomised open-label trial found no significant difference in clinical relapse rates between AZA and mesalamine (Ardizzone 2004). A previous review by this team in 2014 found evidence that purine analogues may be superior to placebo for maintenance of surgically-induced remission in patients with Crohn's disease, although this was based on two small studies (Gordon 2014). The results for efficacy outcomes between purine analogues and 5-ASA agents were uncer-

tain. However, patients taking purine analogues were more likely than 5-ASA patients to discontinue therapy due to adverse events. No firm conclusions could be drawn from the two small studies that compared AZA to infliximab or adalimumab. Adalimumab seemed superior to AZA but further research was needed to confirm these results. Hence, an up-to-date systematic review using the Cochrane Collaboration format was indicated to summarise the current evidence on the use of purine analogues for the maintenance of surgically-induced remission in Crohn's disease.

OBJECTIVES

The primary objective was to evaluate the efficacy and safety of AZA and 6-MP for maintenance of surgically-induced remission in Crohn's disease.

METHODS

Criteria for considering studies for this review

Types of studies

Randomised controlled trials which compared AZA or 6-MP agents to either a no treatment control, placebo or any other active intervention, with treatment durations of at least three months were considered for inclusion.

Types of participants

Participants of any age and sex with a diagnosis of Crohn's disease confirmed by any established method who were in remission following surgery were considered for inclusion. Remission could be defined by a recognized Crohn's disease activity index such as the Crohn's disease activity index (CDAI) or endoscopy, or by participants who have undergone a curative surgical resection, or as defined by the authors of the primary studies. were considered for inclusion. Eligible trials could be conducted in any setting (e.g. single centre or multi-centre).

Types of interventions

The controlled interventions of interest included any randomised controlled trial that compares oral AZA or 6-MP agents to an no treatment, placebo or another active intervention for maintenance of surgically-induced remission. Studies that compare AZA or 6-MP agents to an intervention that focuses on enteral nutrition, oral nutrient supplementation, medical foods, probiotics, parental nutrition or herbal medicines were excluded. We also excluded dose optimisation studies.

Types of outcome measures

Primary outcomes

The primary outcome measure was clinical relapse as defined by the primary studies.

Secondary outcomes

The secondary outcome measures included the proportion of participants who experienced:

- Endoscopic relapse;
- Radiologic relapse;
- Surgical relapse;
- Histologic relapse;
- Adverse event (as defined by FDA 2018. We also noted

where studies failed to provide sufficient information and simply report outcome as 'adverse event');

• Serious adverse events (as defined by FDA 2018. We also noted where studies failed to provide sufficient information and simply report outcome as 'serious adverse event');

- Withdrawal due to adverse events; and
- Health-related quality of life (HRQoL).

Adverse events and serious adverse events that are known to be associated with AZA or 6-MP include:

- Bone marrow suppression: pancytopenia, leucopenia, neutropenia, thrombocytopenia;
- Hypersensitive reactions: malaise, vomiting, diarrhoea, rash, hypotension;
- Malignancy;
- Liver function impairment, jaundice;
- Pancreatitis;
- Pulmonary: pneumonitis; and
- Renal: interstitial nephritis.

The outcome measures were reported at the last time point available (assumed to be at the end of follow-up if not specified) and the time point specified in the methods as being of primary interest (if this was different from the latest time point available). However, it was also indicated when studies reported outcomes at other time points.

Search methods for identification of studies

Electronic searches

For the review update, we searched the following electronic databases from inception to 26 July 2018:

- MEDLINE;
- Embase;
- PubMed;

- CENTRAL; and
- Cochrane IBD Group Specialized Register.

No restrictions were placed on language. Note that the searches were designed to include RCTs conducted on adults and children participants, but to exclude dose optimisation studies and trials that compare AZA or 6-MP agents to oral nutrition supplements (enteral nutrition drinks, tube feeds), medical foods, probiotics, parenteral nutrition, herbal medicines or a combination of these modalities. The search strategy was more than one year old prior to publication of the updated review. Thus, we ran another search from inception to 31 July 2019 prior to publication. The search strategies are reported in [Appendix 1](#).

Searching other resources

Reference searching

We searched reference lists from included articles and any existing relevant reviews. We also searched ongoing trials registered on ClinicalTrials.gov and the WHO International Clinical Trials Registry Platform portal.

Abstracts of major gastroenterology meetings

A manual search of abstracts and proceedings submitted to recent major gastroenterology meetings was performed for the following journals to identify more trials:

- Gastroenterology (American Gastroenterological Association);
- Gut (British Society of Gastroenterology);
- American Journal of Gastroenterology (American College of Gastroenterology); and
- Journal of Pediatric Gastroenterology and Nutrition (European / North American Society of Paediatric Gastroenterology, Hepatology and Nutrition).

If a relevant abstract was identified, details of the full study methodology and results were requested from the authors in order to allow a thorough assessment of the quality of identified studies.

Data collection and analysis

This updated review was based upon the methods described in the published protocol ([Gordon 2014](#)), and in accordance with the Cochrane Handbook for Systematic Reviews of Interventions ([Higgins 2011](#)).

Selection of studies

The selection of studies included the following steps: title screening, abstract screening and full-text review. Two authors (MG and TGH) independently reviewed each article at each stage of selection. Included and excluded studies were recorded. The two authors (MG and TGH) independently screened the titles using the titles of the papers that appeared to have even a minor possibility of inclusion. Adjudication did not occur at the title screening stage and studies that were ambiguous were included by default. The two authors (MG and TGH) then independently screened the abstracts of the articles that report studies with a reasonable possibility of inclusion. Differences in assessment for inclusion were resolved by discussion between the two independent investigators (MG and TGH). Adjudication did not occur at the abstract screening state. Lastly, the two authors (MG and TGH) independently screened the full text which involved selection of articles based on careful examination of the full report. Differences in assessment for inclusion were resolved by discussion between the two independent investigators. Adjudication was performed as needed by a third author (ZIE).

Data extraction and management

A data extraction form was developed to extract information on relevant features and results of included studies. Two authors (ZIE and TGH) independently extracted and recorded data on the pre-defined checklist. Extracted data included the following items:

- Study design: type of RCT, setting, number of interventions, year, author's contact;
- Population characteristics: age, sex, disease distribution, disease duration, site of disease, medication, type and time since operation, total number of participants originally assigned to each treatment group;
- Intervention: type and dose of agent;
- Control: no active treatment, placebo, other drugs;
- Concurrent medications; and
- Outcomes: time of assessment, length of follow up, type of Crohn's disease activity index used, definitions of remission and relapse, site of surgery, relapse rates, adverse events.

Assessment of risk of bias in included studies

Two authors (ZIE and TGH) independently assessed bias using the Cochrane risk of bias tool ([Higgins 2011](#)). Adjudication was performed as needed by a third author (MG). Each domain was assessed as having a low, high, or unclear risk of bias. Domains assessed included:

- Sequence generation (i.e. was the allocation sequence adequately generated?);
- Allocation sequence concealment (i.e. was allocation adequately concealed?);

- Blinding (i.e. was knowledge of the allocated intervention adequately prevented during the study?);
- Incomplete outcome data (i.e. were incomplete outcome data adequately addressed?);
- Selective outcome reporting (i.e. are reports of the study free of suggestion of selective outcome reporting?); and
- Other potential sources of bias (i.e. was the study apparently free of other problems that could put it at a high risk of bias?).

Each domain followed standard definitions used for Cochrane systematic reviews (Higgins 2011). Study authors were contacted for further information when insufficient information was provided to determine the risk of bias.

The overall certainty of the evidence was assessed using the GRADE approach (Guyatt 2008; Schünemann 2011). The GRADE approach appraises the quality of a body of evidence based on the extent to which one can be confident that an estimate of effect or association reflects the item being assessed. Randomised trials start as high quality evidence, but may be downgraded due to: risk of bias (methodological quality), indirectness of evidence, unexplained heterogeneity, imprecision (sparse data) and publication bias. The overall quality of the evidence for each outcome was determined after considering each of these factors and graded as:

- High - we are very confident that the true effect lies close to that of the estimate of the effect;
- Moderate - we are moderately confident in the effect estimate. The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different;
- Low - our confidence in the effect estimate is limited. The true effect may be substantially different from the estimate of the effect; or
- Very low. We have very little confidence in the effect estimate. The true effect is likely to be substantially different from the estimate of effect.

Measures of treatment effect

For binary outcomes, risk ratio (RR) estimates and associated two-sided 95% confidence intervals (CI) were calculated. For nominal or ordinal outcomes, we calculated the RR with corresponding 95% for each category relative to a reference category. For continuous outcomes, we calculated the mean difference (MD) and corresponding 95% CI. If studies in future updates report continuous outcomes that have been measured using different scales (e.g. IBDQ and SF-36), we will calculate the standardised mean difference (SMD) and 95% CI.

Unit of analysis issues

The unit of analysis was the individual participant. We planned to include cross-over trials if data were available from the first phase of the study (i.e. before cross-over occurred). For outcomes where

events recur (e.g. clinical relapses, adverse events), we calculated the proportion of participants who experienced at least one event, individual events were not counted separately. The studies were otherwise not anticipated to have repeated observations of outcomes or multiple treatment events. If studies had randomised subjects to more than one AZA or 6-MP treatment arm, these groups would have been combined for the primary analysis.

Dealing with missing data

We collected information on how each trial handled missing data. When a study appeared to collect and not report all primary outcomes of interest, the original investigators were contacted to request missing data. If the original investigators did not provide the data, this would be noted in the systematic review. For studies with missing dichotomous data, an intention-to-treat analysis was performed where participants with missing data were assumed to have been treatment failures.

Assessment of heterogeneity

We assessed heterogeneity through visual inspection of the forest plots and by calculating the Chi² and I² statistics (Borenstein 2009). For studies that had qualitative homogeneity, statistical heterogeneity was assessed using the Chi² test (a P value < 0.10 was considered statistically significant heterogeneity). The degree of heterogeneity across studies was estimated using the I² statistic. An I² of 25% or less was considered low heterogeneity, 26% to 50% was considered moderate heterogeneity, and 50% and greater was considered substantial heterogeneity. Where sufficient data are available, we planned to explore possible explanations for heterogeneity including factors such as participant characteristics (e.g. age, sex), condition severity, treatment type and dose, and healthcare system/country. Where appropriate, these factors were to be investigated further through sub-group analyses and meta-regression (Borenstein 2009). Where sufficient data are available, we planned to use sensitivity analyses to explore possible causes of methodological heterogeneity (Sutton 2000).

Assessment of reporting biases

If there were an appropriate number of studies in a pooled analysis (i.e. > 10 studies), we planned to investigate potential publication bias using funnel plots (trial effects versus trial size) (Egger 2001). However, the number of studies in each comparison group was smaller than 10.

Data synthesis

Data from individual trials were combined for meta-analysis if the interventions, patient groups and outcomes were sufficiently similar (determined by consensus). We calculated the pooled RR and corresponding 95% CI for dichotomous outcomes. Analyses were grouped by type of intervention treatment (e.g. AZA or 6-MP

versus placebo, AZA or 6-MP versus 5-ASA). Where there were multiple studies in an analysis we used a random-effects model to obtain a more conservative interpretation otherwise, we used a fixed-effect model.

Subgroup analysis and investigation of heterogeneity

We planned to assess the impact of potential effect modifiers such as age of participants (paediatric versus adult studies), drug type (azathioprine versus 6-mercaptopurine) and length of follow-up (12 months or less versus greater than 12 months). There were no studies on children.

Sensitivity analysis

Sensitivity analyses based on random-effects versus fixed-effect models were planned where appropriate data or numbers of studies were available. Sensitivity analysis was also planned to explore possible explanations for significant heterogeneity.

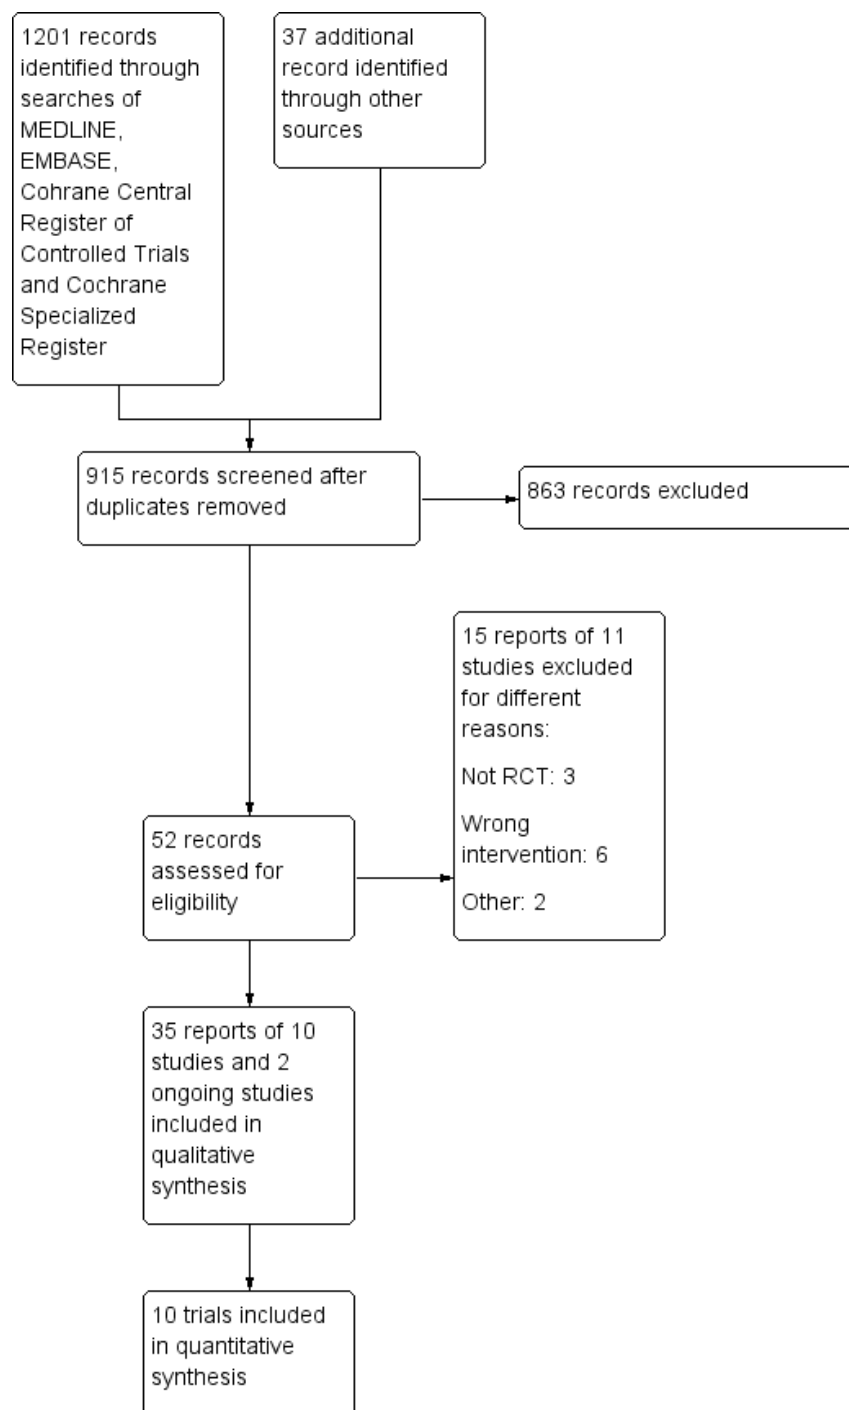

R E S U L T S

Description of studies

Results of the search

The original search for this update was conducted on 26 July 2018. The search expired before the update could be published, so we ran another search on 31 July 2019. The electronic database search conducted on 31 July 2019 identified 1201 records, while 37 records were found through other sources (See [Figure 1](#)). Of the 52 full-text records assessed for eligibility, 35 reports of 10 studies (928 participants) were included in this systematic review update. Two studies ([NCT03185611](#); [NL1344](#)), were classified as ongoing [Characteristics of ongoing studies](#). Eleven studies (15 reports) were excluded for different reasons as presented in the [Characteristics of excluded studies](#) table.

Figure 1. Study flow diagram.

Detailed information about all included studies are presented in the [Characteristics of included studies](#) table.

Included studies

Study design and setting

This systematic review includes reports of single centre and multicentre randomised controlled trials with a parallel design with a duration of 52 weeks ([Lopez-Sanroman 2017](#); [Reinisch 2010](#)), to 36 months ([Mowat 2016](#)). These studies were all published between 2004 and 2017. There were four single-centre studies conducted in two different countries: Italy ([Ardizzone 2004](#); [Armuzzi 2013](#); [Savarino 2013](#)), and Israel ([Scapa 2015](#)). The multicentre studies were conducted across Belgium ([D'Haens 2008](#)), Spain ([Lopez-Sanroman 2017](#)), the UK ([Mowat 2016](#)), or as a multinational collaboration of several countries across Europe and Israel ([Reinisch 2010](#)), and Europe and the USA ([Hanauer 2004](#)). Regarding the care setting, three studies were conducted either in gastroenterology hospitals and medical clinics/centres ([Lopez-Sanroman 2017](#); [Reinisch 2010](#)), and secondary and tertiary hospitals ([Mowat 2016](#)), or as a collaboration between university clinics and hospitals and medical centres in four studies ([Ardizzone 2004](#); [D'Haens 2008](#); [Hanauer 2004](#); [Savarino 2013](#)). The country and care setting were not reported in [Herfarth 2006](#).

Participants

The total number of participants included in nine studies was 928 and ranged from 22 participants ([Armuzzi 2013](#)), to 240 ([Mowat 2016](#)). [Scapa 2015](#) did not clearly report the number of participants randomised. All participants were adults with Crohn's disease who had undergone a resective surgical procedure to remove macroscopic disease. The majority of these participants were recruited within three months of surgery or before hospital discharge, except the 78 participants in [Reinisch 2010](#) who were enrolled between 6 and 24 months postoperatively. Interventions were conducted on participants with quiescent Crohn's disease and the disease activity prior to enrolment was established by generally accepted endoscopic, histological and radiological criteria. However, it is important to note that [Reinisch 2010](#) included participants in subsequent postoperative clinical remission (CDAI < 200), but with signs of moderate to severe endoscopic recurrence. For this reason we only collected data on adverse events from [Reinisch 2010](#).

The age of participants was reported nine studies and ranged between an average of 32.7 years ([Scapa 2015](#)), to 40 years ([D'Haens 2008](#)) in seven trials. Two trials reported age as median ([Armuzzi 2013](#); [Lopez-Sanroman 2017](#)). All studies appear to have been conducted on a male and female adult population. None of the

studies included paediatric participants. [Herfarth 2006](#) did not report any information about the age of participants.

Interventions

All included studies were parallel two arm trials except for two studies that had three intervention arms ([Hanauer 2004](#); [Savarino 2013](#)). The duration of the intervention ranged from 52 weeks ([Armuzzi 2013](#); [Herfarth 2006](#); [Lopez-Sanroman 2017](#); [Reinisch 2010](#); [Scapa 2015](#)), to 24 months ([Ardizzone 2004](#); [D'Haens 2008](#); [Hanauer 2004](#); [Mowat 2016](#); [Savarino 2013](#)).

The studies compared the efficacy of AZA or 6-MP agents with placebo or another active treatment. [Table 1](#) reports a summary of all interventions which are also summarized below:

AZA or 6-MP versus placebo

- AZA versus placebo ([D'Haens 2008](#)).

Both intervention arms also received concomitant metronidazole (750 mg/day) therapy for the first three months of the study ([D'Haens 2008](#)).

- 6-Mercaptopurine versus placebo ([Hanauer 2004](#); [Mowat 2016](#)).

AZA or 6-MP versus oral 5-ASA agents

- AZA versus mesalamine ([Ardizzone 2004](#); [Herfarth 2006](#); [Reinisch 2010](#); [Savarino 2013](#)).
- 6-MP versus mesalamine ([Hanauer 2004](#)).

AZA or 6-MP versus anti-TNF- α

- AZA versus infliximab ([Armuzzi 2013](#)).
- AZA versus adalimumab ([Lopez-Sanroman 2017](#); [Savarino 2013](#)).

In [Lopez-Sanroman 2017](#) both intervention arms also received concomitant metronidazole (750 mg/day) therapy for the first three months of the study.

- 6-Mercaptopurine versus adalimumab ([Scapa 2015](#)).

No studies that compared AZA or 6-MP agents to a no treatment control group were identified.

The use of concurrent treatment was discussed in all but two studies ([Savarino 2013](#); [Scapa 2015](#)). In one study all participants were receiving oral metronidazole (500 mg/day) for two weeks after surgery ([Armuzzi 2013](#)), while in two studies both intervention arms were administered metronidazole (ornidazole) for the first three months after surgery ([D'Haens 2008](#); [Lopez-Sanroman 2017](#)). In [Mowat 2016](#) any concomitant therapy had to be well

documented and there was no reported use of active concomitant treatments. Corticosteroids were allowed to be tapered by standardized stepwise dose reductions in three studies (Ardizzone 2004; D'Haens 2008; Hanauer 2004). Symptomatic treatment with antacids, antidiarrhoeal or spasmolytic medication on demand was permitted in three studies but had to be scrupulously recorded (Ardizzone 2004; D'Haens 2008; Hanauer 2004). D'Haens 2008 permitted topical therapy for perianal disease and cholestyramine for the treatment of bile-acid diarrhoea. Continuous use of nonsteroidal anti-inflammatory drugs was prohibited and only occasional use of paracetamol and tramadol was allowed in Savarino 2013.

Outcomes

Outcomes were reported at multiple time points in two studies (D'Haens 2008; Mowat 2016), and at a single time point in eight studies (Ardizzone 2004; Armuzzi 2013; Hanauer 2004; Herfarth 2006; Lopez-Sanroman 2017; Reinisch 2010; Savarino 2013; Scapa 2015). Some studies had followed participants beyond the intervention period, however, outcome data from those time points were not reported in this review.

Outcomes of interest reported across studies included:

Primary outcomes

- Clinical relapse (Ardizzone 2004; Armuzzi 2013; D'Haens 2008; Hanauer 2004; Herfarth 2006; Lopez-Sanroman 2017; Mowat 2016; Reinisch 2010; Savarino 2013).

Secondary outcome

- Endoscopic relapse (Armuzzi 2013; D'Haens 2008; Hanauer 2004; Mowat 2016; Reinisch 2010; Savarino 2013; Scapa 2015).
- Radiological relapse (Hanauer 2004; Savarino 2013).
- Histologic relapse (Armuzzi 2013).
- Surgical relapse (Ardizzone 2004).
- Adverse events (Ardizzone 2004; D'Haens 2008; Hanauer 2004; Lopez-Sanroman 2017; Reinisch 2010; Savarino 2013).
- Serious adverse events (Ardizzone 2004; Hanauer 2004; Lopez-Sanroman 2017; Mowat 2016; Reinisch 2010).
- Withdrawal due to adverse events (Ardizzone 2004; Armuzzi 2013; D'Haens 2008; Hanauer 2004; Herfarth 2006; Lopez-Sanroman 2017; Mowat 2016; Reinisch 2010; Savarino 2013).

A summary of interventions and outcomes is presented in additional Table 2.

Funding and conflict of interest

Four studies were reportedly supported by pharmaceutical companies (Hanauer 2004; Herfarth 2006; Lopez-Sanroman 2017; Reinisch 2010), but only two declared conflict of interest (Lopez-Sanroman 2017; Reinisch 2010). The author of one study was contacted to clarify the role of the pharmaceutical company and he confirmed that the company had no role in the study design, data analysis or writing of the paper (Hanauer 2004), whereas the remaining authors did not respond. Two studies were not supported by any grant (Armuzzi 2013; Savarino 2013). Savarino 2013 reported no conflicts of interest. Armuzzi 2013 reported receiving educational grants, and consultancy and lecture fees from a pharmaceutical company. Mowat 2016 was funded by a governmental grant and adequately reported on conflicts of interest. Funding and conflict of interest was not reported in two studies (Ardizzone 2004; D'Haens 2008), but our attempt to clarify this by contacting the authors was unsuccessful.

Excluded studies

Eleven studies (15 reports) were excluded for different reasons. The reasons for exclusion for each study are presented in the Characteristics of excluded studies table and are summarised below:

- Three studies were not RCTs (Nos 2000; Reinisch 2013; Robb 2015);
- Six studies assessed the wrong intervention (Ferrante 2015; Mañosa 2013; NCT01876264; Wright 2014; Wright 2015; Zhu 2015);
- One study was terminated due to slow recruitment (NCT02247258); and
- One study assessed the wrong population (Vidigal 2014).

Risk of bias in included studies

The risk of bias was assessed as low in one study (Mowat 2016), high in six studies (Ardizzone 2004; Armuzzi 2013; Herfarth 2006; Lopez-Sanroman 2017; Savarino 2013; Scapa 2015), and unclear in three (D'Haens 2008; Hanauer 2004; Reinisch 2010). Details of the risk of bias assessment are presented in the Characteristics of included studies tables, and in Figure 2 and Figure 3.

Figure 2. Risk of bias summary: review authors' judgements about each risk of bias item for each included study.

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias)	Blinding of outcome assessment (detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias
Ardizzone 2004	+	?	-	?	+	+	+
Armuzzi 2013	?	?	-	-	+	+	+
D'Haens 2008	+	?	?	+	+	+	+
Hanauer 2004	+	+	?	+	+	+	+
Herfarth 2006	+	+	+	+	-	?	?
Lopez-Sanroman 2017	+	+	-	+	+	-	+
Mowat 2016	+	+	+	+	+	+	+
Reinisch 2010	+	+	+	?	+	+	+
Savarino 2013	+	+	-	?	+	+	+
Scapa 2015	?	?	?	?	-	-	?

Figure 3. Risk of bias graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.

Allocation

Random sequence generation

In all of the included studies the allocation of participants to an active treatment or placebo was reported as random. Eight studies were judged as being at low risk of bias for random sequence generation as these studies employed computer-generated randomisation (Ardizzone 2004; D'Haens 2008; Hanauer 2004; Herfarth 2006; Lopez-Sanroman 2017; Mowat 2016; Reinisch 2010; Savarino 2013). Two studies were judged 'unclear' due to insufficient information on the method of randomisation (Armuzzi 2013; Scapa 2015).

Allocation concealment

In six studies the method of allocation concealment was considered adequate (Hanauer 2004; Herfarth 2006; D'Haens 2008; Lopez-Sanroman 2017; Reinisch 2010; Savarino 2013). Four studies were judged as unclear risk of bias for allocation concealment as the methods were not adequately described (Ardizzone 2004; Armuzzi 2013; D'Haens 2008; Scapa 2015).

Blinding

Blinding of participants and personnel

Four of the studies included had an open-label study design and were judged as being at high risk of bias (Ardizzone 2004; Armuzzi 2013; Lopez-Sanroman 2017; Savarino 2013). All the remaining studies were described as double-blind. The method of blinding

was not adequately described in three studies (D'Haens 2008; Hanauer 2004; Scapa 2015), thus these studies were marked as 'unclear'. Two of these studies failed to describe whether the placebo was sufficiently identical to the intervention to blind study participants (D'Haens 2008; Hanauer 2004), and one study provided insufficient information to make a judgement (Scapa 2015). Due to an adequate description of blinding methods, three studies were assessed as having low risk of performance bias (Herfarth 2006; Mowat 2016; Reinisch 2010).

Blinding of outcome assessment

We assessed one study as having a high risk of detection bias (Armuzzi 2013). Four studies were marked as 'unclear' for detection bias, having failed to adequately describe blinding of outcome assessors (Ardizzone 2004; Reinisch 2010; Savarino 2013; Scapa 2015). The rest of the studies were judged as having a low risk of detection bias, for clearly describing the methods regarding blinding of outcome assessment (D'Haens 2008; Hanauer 2004; Herfarth 2006; Lopez-Sanroman 2017; Mowat 2016).

Incomplete outcome data

All except two studies reported data fully and documented drop-outs and reasons for withdrawals. Incomplete outcome data in these studies was due to study termination (Herfarth 2006), and failure to report the number of randomised and withdrawn participants and reasons for withdrawal (Scapa 2015). The authors of

Scapa 2015 were contacted for clarification, however no additional information was provided, except that the study is under preparation for publication. An 'unclear' judgment for this domain was not made for any of the studies.

Selective reporting

Trial registration was available for four studies (Lopez-Sanroman 2017; Mowat 2016; Reinisch 2010; Scapa 2015). Seven studies were judged as being at low risk of bias for reporting all outcomes prespecified in the trial registration or in the methods section of the study manuscript (Ardizzone 2004; Armuzzi 2013; D'Haens 2008; Hanauer 2004; Mowat 2016; Reinisch 2010; Savarino 2013). One study was judged to be 'unclear' (Herfarth 2006). Two studies were marked 'high' for reporting bias: Scapa 2015 failed to report outcomes prespecified in the trial registration and Lopez-Sanroman 2017 did not adequately report on a prespecified outcome.

Other potential sources of bias

Eight studies were judged to be at low risk of bias for other apparent sources of potential bias. Two studies provided insufficient information to enable the reviewers make a judgement and were rated as 'unclear' (Herfarth 2006; Scapa 2015).

Effects of interventions

See: [Summary of findings for the main comparison](#) Azathioprine or 6-mercaptopurine compared to placebo for maintenance of surgically-induced remission in Crohn's disease; [Summary of findings 2](#) Azathioprine or 6-mercaptopurine compared to 5-aminosalicylic acid for maintenance of surgically-induced remission in Crohn's disease; [Summary of findings 3](#) Azathioprine or 6-mercaptopurine compared to anti TNF- α for maintenance of surgically-induced remission in Crohn's disease

AZA or 6-MP versus placebo

Three studies that compared AZA (100 to 150 mg/day) or 6-MP in doses of 50 mg/day and 1 mg/kg/day to placebo were identified (D'Haens 2008; Hanauer 2004; Mowat 2016). In one of these studies all participants were also taking either metronidazole or ornidazole (750 mg/day) for the first three months of intervention (D'Haens 2008).

Primary outcome

Clinical relapse

Three studies reported on clinical relapse, with definitions for clinical relapse varying across studies. D'Haens 2008 defined clinical

relapse as a CDAI > 250. Mowat 2016 defined clinical relapse as a CDAI > 150 and a 100 point increase in CDAI from baseline. Hanauer 2004 defined relapse as a clinical recurrence grading score > 2. There was moderate certainty evidence that AZA or 6-MP are more efficient in preventing clinical relapse than placebo ([Analysis 1.1](#); [Summary of findings for the main comparison](#)). After a follow-up of 12 to 36 months, 51% (109/215) of participants in the AZA/6-MP group relapsed compared to 64% (124/193) of the placebo group (RR 0.79; 95% CI 0.67 to 0.92; 408 participants; 3 studies; $I^2 = 0\%$; GRADE moderate certainty evidence). The subgroup analysis found no evidence of a difference in clinical relapse between AZA and 6-MP ($P = 0.34$). A subgroup analysis based on length of follow-up found no evidence of a difference in clinical relapse when measured at 12 months or less or at over 12 months ($P = 0.34$).

Secondary outcomes

The effect on endoscopic relapse rate as well as the tolerability and safety of AZA/6-MP agents compared to placebo was uncertain, due to very low to low certainty evidence ([Summary of findings for the main comparison](#)).

Endoscopic relapse

Endoscopic relapse ([Analysis 1.3](#)), defined as endoscopic score ≥ 2 , was reported in two studies (D'Haens 2008; Mowat 2016). During a follow-up period of 12 to 36 months, 67% (112/168) of AZA/6-MP participants relapsed endoscopically, compared to 75% (115/153) of placebo participants (RR 0.85; 95% CI 0.64 to 1.13; 321 participants; 2 studies; $I^2 = 62\%$; GRADE low certainty evidence). We found no evidence of a difference in endoscopic relapse rates between AZA and 6-MP ($P = 0.11$). A subgroup analysis based on length of follow-up found no evidence of a difference in endoscopic relapse rates measured at different times ($P = 0.11$). Hanauer 2004 compared endoscopic relapse rates (defined as $i \geq 2$) between the 6-MP (16%; 95% CI 7% to 35%) and placebo (42%; 95% CI 21% to 70%) groups at 24 months (HR 0.48; reported $P = 0.13$; 87 participants). However, these data were insufficiently reported to be included in the meta-analysis.

Radiologic relapse

Radiologic relapse rate defined as a radiographic recurrence grading score ≥ 2 was reported in Hanauer 2004. After 24 months, 33% (95% CI, 19% to 54%) of participants treated with 6-MP had radiologic relapse compared to 49% (95% CI, 30% to 72%) in the placebo group (HR, 0.61; reported $P = 0.19$; 84 participants).

Adverse events, serious adverse events and withdrawal due to adverse events

There was no clear difference in the number of participants who experienced adverse events, serious adverse events or withdrawal

due to adverse events when AZA/6-MP drugs are compared to placebo. Adverse events ([Analysis 1.5](#)) were reported in two studies ([D'Haens 2008](#); [Hanauer 2004](#)). For the follow-up period of 12 to 24 months, 14% (12/87) of AZA/6-MP participants experienced at least one adverse event that was possibly related to treatment compared to 10% (8/81) of the placebo participants (RR 1.36; 95% CI 0.57 to 3.27; 168 participants; 2 studies; $I^2 = 0\%$; GRADE low certainty evidence). The subgroup analysis found no evidence of a difference in adverse events when AZA and 6-MP were compared ($P = 0.32$). A subgroup analysis based on length of follow-up found no evidence of a difference in adverse events when measured at 12 months or less and over 12 months ($P = 0.32$). Commonly reported adverse events included hair loss, leukopenia, diarrhoea, abdominal pain, hepatotoxicity and arthralgia. Two studies ([Hanauer 2004](#); [Mowat 2016](#)), reported on serious adverse events ([Analysis 1.7](#)), and three studies reported on the number of withdrawn participants as a result of adverse reactions to the treatment ([D'Haens 2008](#); [Hanauer 2004](#); [Mowat 2016](#)). About 3% (5/175) of AZA/6-MP participants and 1% (2/152) of placebo participants experienced serious adverse events during 12 to 36 months of intervention follow-up (RR 1.78; 95% CI 0.39 to 8.18; 327 participants; 2 studies; $I^2 = 0\%$; GRADE low certainty evidence). During the same period, almost an equal proportion of AZA/6-MP (24%; 51/215) and placebo (25%; 49/193) participants were withdrawn from the study due to adverse events (RR 0.90; 95% CI 0.63 to 1.29; 408 participants; 3 studies; $I^2 = 3\%$; GRADE moderate certainty evidence). A subgroup analysis found no evidence of a difference in withdrawal due to adverse events when AZA and 6-MP were compared ($P = 0.69$). A subgroup analysis based on length of follow-up found no evidence of a difference in withdrawals due to adverse events when measured at 12 months or less or at over 12 months ($P = 0.69$). Commonly reported serious adverse events included arthralgia, pancreatitis, leucopenia and bowel obstruction. Adverse events leading to withdrawal from the study included abnormal blood results leading to led to temporary discontinuation of treatment in 28% of the participants. However, specific details on reasons for discontinuation were not clearly reported.

Health related quality of life

HRQoL was reported in one study with no difference in IBDQ scores between the two treatments group. However these data were insufficiently reported for inclusion in the analysis ([Mowat 2016](#)).

AZA or 6-MP versus 5-ASA

A total of five studies compared the efficacy of AZA (2 to 2.5 mg/day) or 6-MP (50 mg/day) to mesalamine (dose 3 to 4 g/day) ([Ardizzone 2004](#); [Hanauer 2004](#); [Herfarth 2006](#); [Reinisch 2010](#); [Savarino 2013](#)). Due to the specific inclusion/exclusion criteria in [Reinisch 2010](#) ([Characteristics of included studies](#)), the clinical

and endoscopic relapse data from this study were not included in meta-analyses.

Primary outcome

Clinical relapse

Clinical relapse defined as a clinical recurrence grading score ≥ 2 ([Hanauer 2004](#); [Savarino 2013](#)), or a CDAI ≥ 200 ([Ardizzone 2004](#)), was reported in four studies. There was low certainty evidence on the efficacy of AZA or 6-MP for maintaining post-operative clinical remission in comparison to 5-ASA compounds ([Analysis 2.1](#); [Summary of findings 2](#)). At the end of the 24 month follow-up, 64% (113/177) of AZA treated participants clinically relapsed compared to 59% (101/170) of 5-ASA treated ones (RR 1.05, 95% CI 0.89 to 1.24, 347 participants, 4 studies, $I^2 = 8\%$; GRADE low certainty evidence). We carried out a subgroup analysis and found no evidence of a difference in clinical relapse rates between AZA and 6-MP ($P = 0.18$). A subgroup analysis based on length of follow-up found no evidence of a difference in clinical relapse rates when measured at 12 months or less or at over 12 months ($P = 0.97$).

Secondary outcomes

Endoscopic relapse

Endoscopic relapse was reported in one study ([Savarino 2013](#)), and was defined as a Rugeerts score ≥ 2 . The efficacy of AZA in comparison to 5-ASA formulations in preventing endoscopic relapse was uncertain, as the certainty of evidence was very low ([Analysis 2.3](#); [Summary of findings table 2](#)). After 24 months, 65% (11/17) of AZA participants relapsed endoscopically compared to 83% (15/18) of 5-ASA participants (RR 0.78; 95% CI 0.52 to 1.17; 35 participants; 1 study; GRADE very low certainty evidence).

Radiologic relapse

Radiologic relapse (follow-up 24 months), defined as radiographic recurrence grading score ≥ 2 , was reported in one study ([Savarino 2013](#)) and meta-analysis was not performed. There is a very low certainty evidence regarding the effect of purine analogues on radiologic relapse rate compared to 5-ASA drugs ([Analysis 2.4](#)). Sixty-four percent (13/17) of AZA participants experienced radiologic relapse compared to 83% (15/18) of 5-ASA participants (RR 0.92; 95% CI 0.66 to 1.28; 35 participants; 1 study; GRADE very low certainty evidence).

Endoscopic and radiologic relapse rates were reported by [Hanauer 2004](#), however the results were insufficient to be included in the

meta-analysis. At 24 months (participants 91), reported endoscopic and radiologic relapse rates were 16%; 95% CI 7% to 35% and 33%; 95% CI 19% to 54% in the purine antimetabolites compared to 48%; 95% CI 30% to 70% and 46%; 95% CI 29% to 66% in the mesalamine intervention respectively.

Surgical relapse

Surgical relapse (follow-up 24 months), defined as the need for another surgery was reported in [Ardizzone 2004](#). The effect of purine analogues compared to 5-ASA for the maintenance of surgical remission was uncertain, because the quality of evidence was judged as very low ([Analysis 2.5](#); [Summary of findings 2](#)). During the follow-up period of two years, the proportion of participants with surgical relapse was 37% (26/71) in the 5-ASA group versus 30% (21/71) in the purine analogues group (RR 0.81; 95% CI 0.50 to 1.29; 142 participants; 1 study; GRADE very low certainty evidence).

Adverse events, serious adverse events and withdrawal due to adverse events

Adverse events and withdrawal due to adverse events were reported in four studies ([Ardizzone 2004](#); [Hanauer 2004](#); [Reinisch 2010](#); [Savarino 2013](#)), and five studies respectively ([Ardizzone 2004](#); [Hanauer 2004](#); [Herfarth 2006](#); [Reinisch 2010](#); [Savarino 2013](#)), while serious adverse events were reported in three studies ([Ardizzone 2004](#); [Hanauer 2004](#); [Reinisch 2010](#)). The effect of purine analogues when compared to 5-ASA drugs on adverse events was uncertain, as the quality of evidence was low ([Summary of findings 2](#)). During a follow-up of 12 to 24 months, the proportion of participants who experienced at least one adverse event ([Analysis 2.6](#)) was 41% (73/176) and 48% (81/170) in the AZA/6-MP and 5-ASA groups respectively (RR 0.89; 95% CI 0.74 to 1.07; 346 participants; 4 studies; $I^2 = 15\%$; GRADE low certainty evidence). We found no evidence of a difference in adverse events when we carried out a subgroup analysis comparing AZA to 6-MP ($P = 0.34$). A subgroup analysis based on length of follow-up found no evidence of a difference in adverse events when measured at 12 months or less or at over 12 months ($P = 0.66$). Commonly reported adverse events included leukopenia, abdominal pain, nausea, nasopharyngitis, diarrhoea and headache. During a 12 to 24 months follow-up, serious adverse events ([Analysis 2.8](#)) were experienced by 17% (27/159) of purine analogue participants compared to 4% (6/152) of 5-ASA participants (RR 3.39; 95% CI 1.26 to 9.13; 311 participants; 3 studies; $I^2 = 9\%$; GRADE very low certainty evidence). We found no evidence of a difference in serious adverse events when we carried out a subgroup comparing AZA to 6-MP ($P = 1.0$). A subgroup analysis based on length of follow-up found no evidence of a difference in serious adverse events when measured at 12 months or less or at over 12 months ($P = 0.19$). Commonly reported serious adverse

events include postoperative bowel obstruction. The proportion of participants that withdrew from the trial due to an adverse event ([Analysis 2.10](#)) during 12 to 24 months follow-up were 19% (42/218) versus 8% (16/207) in the AZA/6-MP and 5-ASA groups respectively (RR 2.21, 95% CI 1.28 to 3.81; participants = 425; studies = 5; $I^2 = 0\%$; GRADE low certainty evidence). We found no evidence of a difference in withdrawals due to adverse event when AZA and 6-MP were compared ($P = 0.25$). A subgroup analysis based on length of follow-up found no evidence of a difference in withdrawal due to adverse events when measured at 12 months or less or at over 12 months ($P = 0.46$). Adverse events leading to withdrawal included severe epigastric intolerance, increase in liver function test results, leukopenia and acute pancreatitis.

HRQoL

Two studies with a follow-up of 12 to 24 months reported on HRQoL based on the IBDQ score ([Reinisch 2010](#); [Savarino 2013](#)). The effect of 5-ASA agents on HRQoL was uncertain as a result of serious limitations due to unclear risk of performance and outcome assessment bias and high risk of performance bias and outcome assessment bias in each study respectively and very serious limitations due to sparse data in both studies. [Savarino 2013](#) reported on the proportion of participants with an IBDQ score > 170 (ranging from 32 to 224), which is regarded as a symptomatic remission score ([Analysis 2.12](#)). After 24 months of follow-up, 12% (2/17) of AZA treated participants reported an IBDQ score > 170 compared with 17% (3/18) of 5-ASA participants (RR 0.71; 95% CI 0.13 to 3.72; 35 participants; 1 study; GRADE very low certainty evidence). [Reinisch 2010](#), assessed HRQoL based on the mean change of IBDQ scores compared to baseline ([Analysis 2.13](#)). At 12 months, the mean IBDQ difference compared to baseline was 9 (SD 17.7) in the AZA group versus 5 (SD 27.4) in the 5-ASA treated group (MD 4; CI 14.36 to -6.36; 78 participants; 1 study; GRADE very low certainty evidence).

AZA or 6-MP versus anti-TNF- α

Three studies comparing AZA to either infliximab ([Armuzzi 2013](#)), or adalimumab ([Lopez-Sanroman 2017](#); [Savarino 2013](#)), and one study comparing 6-mercaptopurine to adalimumab ([Scapa 2015](#)), were identified. For all of the studies, the intervention started within 45 days of surgery. In the [Lopez-Sanroman 2017](#) study all participants were also administered metronidazole (750 mg/day) for the first three months of the study. The total number of assessed participants was 157.

Primary outcome

Clinical relapse

Clinical relapse ([Analysis 3.1](#)) was reported in three studies ([Armuzzi 2013](#); [Lopez-Sanroman 2017](#); [Savarino 2013](#)), and was defined as HBI ≥ 2 ([Armuzzi 2013](#)), clinical recurrence grading score ≥ 2 ([Savarino 2013](#)) or CDAI score >200 ([Lopez-Sanroman 2017](#)). The certainty of evidence that AZA is inferior in preventing postsurgical clinical relapse compared to anti-TNF- α agents was very low ([Summary of findings 3](#)). During a follow-up of 12 to 24 months, 43% (29/67) of participants treated with AZA clinically relapsed compared to 14% (10/72) of participants in the anti-TNF- α group (RR 2.89, 95% CI 1.50 to 5.57, 139 participants, 3 studies, $I^2 = 0\%$; GRADE very low certainty evidence). The subgroup analysis based on length of follow-up found no evidence of a difference in clinical relapse when measured at 12 months or less or at over 12 months ($P = 0.2$).

Secondary outcomes

Endoscopic relapse

Endoscopic relapse was reported in four studies and was defined as Rutgeerts score ≥ 2 . The evidence that purine antimetabolites are less efficient than anti-TNF- α for maintaining endoscopic remission was very low ([Analysis 3.3](#); [Summary of findings 3](#)). The proportion of purine analogue participants with endoscopic relapse was 58% (43/74) compared to 26% (22/83) of anti-TNF- α participants (RR 3.67; 95% CI 1.05 to 12.81; 157 participants; 4 studies; $I^2 = 64\%$; GRADE very low certainty evidence). We found no evidence of a difference in endoscopic relapse rates when we carried out a subgroup analysis to compare AZA to 6-MP ($P = 0.72$). A subgroup analysis based on length of follow-up found a quantitative difference in endoscopic relapse when measured at 12 months or less or at over 12 months ($P = 0.2$).

Radiologic relapse

Radiologic relapse was reported in two studies, defined either as radiographic recurrence grading score ≥ 2 ([Savarino 2013](#)), or based on magnetic resonance enterography scores MR2 and MR3 ([Lopez-Sanroman 2017](#)). The certainty of evidence that purine analogues are less efficient to prevent endoscopic relapse than adalimumab or infliximab was very low ([Analysis 3.5](#); [Summary of findings 3](#)). The proportion of participants with endoscopic relapse after 12 to 24 months follow-up was 69% (39/56) and 38% (23/61) among the purine analogues and anti-TNF- α treated groups respectively. Data pooling for [Savarino 2013](#) (RR 1.36, 95% CI 0.94 to 1.98) and [Lopez-Sanroman 2017](#) (RR 12.24, 95% CI 1.8 to 83.12) was not feasible due to considerable heterogeneity ($I^2 = 85\%$). The certainty of evidence was rated very low due to high risk of bias and very serious imprecision.

Histologic relapse

Histologic relapse ([Analysis 3.6](#)), based on the scoring system modified by [Regueiro 2009](#) was reported only in [Armuzzi 2013](#) and a meta-analysis was not performed. Histologic relapse during 12 months of follow-up was detected in 82% (9/11) and 18% (2/11) participants of the AZA and infliximab groups respectively (RR 4.50; 95% CI 1.25 to 16.25).

Adverse events, serious adverse events and withdrawal due to adverse events

Adverse events were reported in two studies ([Lopez-Sanroman 2017](#); [Savarino 2013](#)). Withdrawals due to adverse events were reported in three studies ([Armuzzi 2013](#); [Lopez-Sanroman 2017](#); [Savarino 2013](#)), and serious adverse events were reported in one study ([Lopez-Sanroman 2017](#)). The certainty of evidence regarding tolerability and safety of purine analogues in comparison to anti-TNF- α agents ranged from very low to low ([Summary of findings 3](#)). There was no clear difference in the number of participants who experienced adverse events when AZA/6-MP was compared to anti-TNF- α during the follow-up of 12 to 24 months ([Analysis 3.7](#)). Fifty-seven per cent (32/56) of AZA/6-MP participants experienced at least one adverse event compared to 51% (31/61) of the anti-TNF- α group (RR 1.13; 95% CI 0.83 to 1.53; 117 participants; 2 studies; $I^2 = 0\%$; GRADE low certainty evidence). A subgroup analysis based on length of follow-up found no evidence of a difference in adverse events when measured at 12 months or less or at over 12 months ($P = 0.65$). Commonly reported adverse events included bronchitis, nasopharyngitis, arthralgia, nausea and abscess ([Savarino 2013](#)). Full details concerning adverse events were not reported in [Lopez-Sanroman 2017](#). The evidence regarding serious adverse events comes from a single study and a meta-analysis was not performed ([Analysis 3.9](#)). The proportion of participants with serious adverse events was 10% (4/39) and 20% (9/45) among the AZA and adalimumab groups respectively (RR 0.51; 95% CI 0.17 to 1.54; 84 participants; 1 study; GRADE very low certainty evidence). The types of serious adverse events were not described. Over a follow-up that ranged from 12 to 24 months, 16% (11/67) of AZA/6-MP treated participants were withdrawn from the study due to an adverse event compared to 3% (2/72) of the anti-TNF- α treated participants (RR 3.97; 95% CI 0.92 to 17.22; 139 participants; 3 studies; $I^2 = 4\%$; GRADE low certainty evidence). A subgroup analysis based on length of follow-up found no evidence of a difference in withdrawals due to adverse events when measured at 12 months or less or at over 12 months ($P = 0.24$). Adverse events leading to withdrawal included severe nausea, leukopenia, arthralgia, urothelial carcinoma, dyspepsia, dyspnoea, death, atopic dermatitis and abdominal pain with increase in pancreatic enzymes.

Health related quality of life

A single study assessed health-related quality of life ([Savarino 2013](#)). At 24 months, an IBDQ > 170 was recorded in 12% (2/17) of participants treated with AZA compared to 88% (14/16) treated with adalimumab (RR 0.13; 95% CI 0.04 to 0.50; 34 participants; 1 study). This outcome was also evaluated in [Lopez-Sanroman 2017](#) using the EuroQol-5 dimensions questionnaire, however reported data were insufficient to be included in meta-analysis.

Special safety note

It is worth specifically noting that two adverse events leading to therapy cessation occurred in more than 1% of participants treated

with purine analogues. Pancreatitis was a serious adverse event that led to withdrawal across several of the studies. However, the rate of occurrence was almost exclusively in participants receiving purine analogues (11 cases in 354 participants taking purine analogues, 3.1%) compared to no occurrences in any of the comparison groups (i.e. placebo, 5-ASA or anti-TNF- α) in this review. Leucopenia occurred also almost exclusively in participants receiving purine analogues (9 cases in 354 participants, 2.5%) compared to no occurrences in all other groups.

ADDITIONAL SUMMARY OF FINDINGS *[Explanation]*

Azathioprine or 6-mercaptopurine compared to 5-aminosalicylic acid for maintenance of surgically-induced remission in Crohn's disease						
Patient or population: People with surgically-induced remission in Crohn's disease Setting: Outpatient Intervention: Azathioprine (2 mg/kg/day) or 6-mercaptopurine (50 mg/day) Comparison: 5-aminosalicylic acid						
Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	No. of participants (studies)	Certainty of the evidence (GRADE)	Comments
	Risk with 5-aminosalicylic acid	Risk with Azathioprine or 6-mercaptopurine				
Clinical relapse Follow-up: 12 to 24 months	Study population		RR 1.05 (0.89, 1.24)	347 (4 RCTs)	⊕⊕○○ LOW ¹²	Clinical relapse defined as a clinical grading score ≥ 2 (Hanauer 2004 ; Savarino 2013) or CDAI ≥ 200 (Ardizzone 2004)
	556 per 1,000	595 per 1,000 (456 to 773)				
Endoscopic relapse Follow-up: 24 months	Study population		RR 0.78 (0.52 to 1.17)	35 (1 RCT)	⊕○○○ VERY LOW ¹³	Endoscopic relapse defined as a Rugeerts score ≥ 2 (Savarino 2013)
	833 per 1,000	650 per 1,000 (433 to 975)

GRADE Working Group grades of evidence

High certainty: We are very confident that the true effect lies close to that of the estimate of the effect

Moderate certainty: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

Low certainty: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect

Very low certainty: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect

¹ Downgraded one level due to high risk of bias

² Downgraded two levels due to very serious imprecision (39 events)

³ Downgraded one level due to serious imprecision (65 events)

⁴ Downgraded one level due to substantial heterogeneity ($I^2 = 64\%$)

⁵ Downgraded one level due to serious imprecision (63 events)

⁶ Downgraded two levels due to very serious imprecision (13 events)

DISCUSSION

Summary of main results

Ten RCTs assessing the effectiveness of AZA and 6-MP for maintaining surgically-induced remission in Crohn's disease were studied. The studies recruited people with Crohn's disease over the age of 16 years who were in surgically-induced remission. The participants were randomised after surgery to received AZA or 6-MP, placebo, 5-ASA agents or anti-TNF- α agents.

We found moderate certainty evidence that AZA and 6-MP are superior to placebo for preventing post-surgical clinical relapse in Crohn's disease. There was low certainty evidence on the safety of AZA and 6-MP when adverse events and serious adverse events were considered. The certainty of the evidence for withdrawal due to adverse events was moderate. This was due to imprecision resulting from very sparse data.

There was no clear difference clinical relapse when AZA or 6-MP was compared with 5-ASA. There are considerable concerns raised with the safety profile of AZA and 6-MP. For the safety outcome serious adverse events and withdrawals due to adverse events, 5-ASA was found to be superior to AZA and 6-MP. However, the certainty of evidence for the efficacy and safety outcomes were low due to high risk of performance bias and sparse data.

There was very low certainty evidence that AZA and 6-MP may be inferior to anti-TNF- α agents for preventing clinical relapse. We also found no clear difference in adverse events, serious adverse events or withdrawals due to adverse events when both outcomes were compared. This was also based on low certainty evidence. The evidence was downgraded due to high risk of performance bias and sparse data, therefore, the results should be interpreted with caution.

Overall completeness and applicability of evidence

We consider the evidence from this review to be applicable to most patients with post-surgical remission of Crohn's disease. The evidence only assesses AZA or 6-MP compared with placebo, 5-ASA or anti-TNF- α agents. All outcomes which we had aimed to analyse were reported in the studies. However, other measures of relapse (endoscopic, histologic and surgical) and health related quality of life were sparsely reported. This meant that very little data were available for our analysis. The review found moderate certainty evidence on the efficacy of AZA and 6-MP compared with placebo. This can be considered complete and not requiring new studies, however, the evidence comparing it with 5-ASA and anti-TNF- α were of very low or low certainty. Therefore, additional studies may change the results. The use of concomitant treatments such as antidiarrhoeal agents, corticosteroids and antibiotics were reported in some studies. The circumstances in

which these treatments were given were noted in the studies and judged to be reflective of clinical practice.

Quality of the evidence

The certainty of the evidence was rated very low to moderate. Overall, six studies were at high risk of bias and three were at unclear risk of bias. Downgrading for limitations was mostly due to lack of blinding and this was particularly common with the head to head comparisons of active drugs. For most of the outcomes, there was imprecision due to sparse data as the number of events ranged between seven and 154. For the clinical relapse outcome, the optimal information size was obtained from power calculations in the largest and most recent study (Mowat 2016). Most of the results were consistent except in two instances where there was substantial statistical heterogeneity (I^2 between 62% and 64%). There was no indirectness as all the studies in the review met the criteria proposed in the scope of the review. We were unable to assess for publication bias due to insufficient data.

Potential biases in the review process

We attempted to reduce potential biases in the review process. A comprehensive literature search was performed to identify all eligible studies. Two review authors independently assessed studies for inclusion, extracted data and assessed study quality.

All analyses were completed using the intention-to-treat principle, whereby participants with final missing outcomes were assumed to have relapsed. Given the high attrition rate in the purine analogue groups compared to the 5-ASA groups, this may have affected the difference in clinical relapse rates between purine analogues and 5-ASA. However, it is arguably a moot point given that even if purine analogues did have superior efficacy, it is difficult to rationalise the use on the basis of the poor adverse event profile in the published evidence.

One of the included studies administered active concomitant treatments in both intervention arms. This was considered a source of clinical heterogeneity in analyses that included studies which had no concomitant treatments. We did not remove this study from the analyses as a sensitivity analysis showed no difference in the results.

Agreements and disagreements with other studies or reviews

A recent Cochrane review assessing the use of AZA or 6-MP for maintenance of medically-induced remission in Crohn's disease revealed that the purine analogues are more effective than placebo, with higher response rates for AZA than 6-MP (Chande 2015). These findings are mirrored in the four studies comparing purine analogues to placebo. No difference in efficacy was found between

AZA or 6-MP and 5-ASA. This could be due to lower disease activity following resection of the gut than is achieved in medically-induced remission of Crohn's disease, so that a milder anti-inflammatory agent such as 5-ASA, gives a better risk versus benefit ratio when compared to AZA and 6-MP. It is also possible that the methodology of the included studies supports this hypothesis, with all but one study recruiting participants in the immediate post-surgical setting. As such, the participants are potentially at their lowest period of disease activity clinically and microscopically. The findings regarding safety are also consistent with the two most common adverse events noted as pancreatitis and leucopenia.

A Cochrane review looking at the use of 5-ASA for the maintenance of surgically-induced remission in Crohn's disease suggests that 5-ASA may be superior to placebo (Gjuladin-Hellon 2019). It also suggested that 5-ASA is a safe and well-tolerated drug, as the incidence of adverse events was not different in participants receiving 5-ASA compared to those receiving placebo. The results of this systematic review question the risk versus benefit balance of starting a purine analogue over 5-ASA in postoperative Crohn's disease.

The international guidance from the European Crohn's and colitis Organisation (ECCO) updated in 2016 is consistent with the findings of this review in that they do indicate a role for purine analogues (Gionchetti 2016), although they do not comment on the limitations of the evidence as identified in this review. Most importantly, the significant safety questions raised in the synthesis performed in this review are not discussed within the ECCO documents in this context (section 8G), although leucopenia is noted in medical induced remission maintenance (6E). The National Institute for Clinical and Care Excellence (NICE) in the UK suggests AZA as first line therapy in this context (NICE 2016), citing the previous version of this review in their 2016 guidance (Gordon 2014). Unlike ECCO, the NICE guidance makes no specific mention of safety concerns. Given one of the specific adverse events noted frequently (leucopenia) is recognised in the context

of purine analogues, it is important to highlight that the risk of pancreatitis has not been highlighted in either guideline, despite being recognised as the most common serious adverse events in both Cochrane reviews on these medications.

AUTHORS' CONCLUSIONS

Implications for practice

Moderate certainty evidence suggests that purine analogues may be superior to placebo for maintenance of surgically-induced remission in participants with Crohn's disease. There was no clear difference in the number of clinical relapses when purine analogues were compared with 5-ASA agents, however this is based on low certainty evidence and no firm conclusions can be drawn. However, participants taking purine analogues were more likely than 5-ASA participants to experience serious adverse events and discontinue therapy due to adverse events. Very low certainty evidence suggests that AZA and 6-MP may be inferior to anti-TNF- α agents, however, no firm conclusions can be drawn.

Implications for research

Further research investigating the efficacy and safety of AZA and 6-MP in comparison to other active medications in surgically-induced remission of Crohn's disease is warranted.

ACKNOWLEDGEMENTS

Funding for ZIE, TH, and partial funding for MG was provided through a larger NIHR Cochrane Programme Grant in the UK.

Funding for the Cochrane IBD Group (May 1, 2017 to April 30, 2022) has been provided by Crohn's and Colitis Canada (CCC).

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Ardizzone 2004

Methods	<p>Study design: RCT, single centre</p> <p>Setting: University "L.Sacco" Hospital (Milan, Italy), 1994 to 2001</p>
Participants	<p>Inclusion: Adult (18 to 70 years) participants who underwent surgery for symptomatic intestinal stenosis or occlusion, which is clinically quiescent (CDAI \leq 150) able to start oral nutrition and oral medication within the first 2 postoperative weeks</p> <p>Exclusion: Contraindications for use of mesalamine or AZA and pre-existing hepatic disease, renal dysfunction, clinically important lung disease, systemic infection, short-bowel syndrome, presence of alcoholic stoma, history of cancer, hypersensitivity to mesalamine or AZA, erythrocyte macrocytosis, use of immunosuppressive drugs in the past 3 months; participants who had received treatment with anti-TNF-α within the 6 months before surgery; pregnancy/breastfeeding; participants who had undergone surgical procedures other than conservative surgery or for perianal disease only; history of corticosteroid-dependent disease</p> <p>Age (IG1 / IG2) mean: 38.4 years</p> <p>Sex (M:F): 95: 52 overall; (45:26) versus (50:26)</p> <p>Type of surgery: Stricturoplasty- 36; Minimal bowel resection- 70; Minimal bowel resection stricturoplasty-36</p> <p>Previous surgery (IG1+IG2): 69/142 overall (38/71) versus (31/71)</p> <p>Start of intervention after surgery: < 2 weeks</p> <p>Medication use (IG1+ IG2): Mesalamine or sulphasalazine 62; Corticosteroids 41; Immunosuppressants 9; None 30</p> <p>Smoker (IG1 / IG2): (28/71) versus (36/71)</p> <p>Number randomised (N = 142): 71 versus 71</p> <p>Number analysed (N = 138): (69/71) versus (69/71) - ITT; 50/71 versus 61/71 - per protocol</p> <p>Post-randomisation exclusion (n = 11): (6/71) versus (5/71) (did not start the treatment -3 (2 versus 1); lost to follow-up -8 (4 versus 4))</p>
Interventions	<p>Group 1: Azathioprine administered at a dosage of 2 mg/kg/day</p> <p>Group 2: Mesalamine was administered at a dosage of 3 g/day divided into 3 doses</p> <p>All participants: treatment with aminosaliclates, metronidazole, and any other CD-specific treatment had to be discontinued. Corticosteroids were allowed to be tapered by standardized stepwise dose reductions within 6 weeks after surgery at the latest. Symptomatic treatment with antacids, antidiarrhoeal agents, or spasmolytic agents was allowed but had to be scrupulously recorded. Compliance with treatment was evaluated by a simple questionnaire in which adverse events were also recorded. Participants receiving AZA were regularly assessed by total blood cell count and serum transaminase values to monitor any myelotoxicity and hepatotoxicity of the treatment. Participants were seen at baseline and every 6 months</p>

Outcomes	<p>Duration of study: 24 months</p> <p>1. Clinical relapse defined as the presence of symptoms related to CD, variably associated with radiologic, endoscopic, and laboratory findings, with a CDAI score > 200, which is considered severe enough to warrant treatment with a systemic corticosteroid at a medium-high dose</p> <p>2. Surgical Relapse defined as the presence of symptoms refractory to medical treatment or complications requiring another surgical procedure (e.g., occlusive disease, intra-abdominal abscesses, or high-flow fistulas)</p> <p>3. Adverse events</p>
Notes	<p>Funding source: Not reported</p> <p>Conflict of interest: Not reported</p> <p>Power calculation: Based on a maximum relapse rate at 2 years of 45% mesalamine, 62 participants per treatment group was considered sufficient to detect a difference of $\geq 25\%$ for the AZA treatment group (type 1 error of 5%). The number of participants in each group was increased to 68 to compensate for an anticipated drop out rate of 10%</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "After surgery, patients who met the inclusion criteria and who agreed to enter the study were randomised to receive mesalamine or AZA by a computer-generated list" and "Randomization was performed in blocks of 10" Comment: computer generated block randomisation
Allocation concealment (selection bias)	Unclear risk	Insufficient information to make judgment
Blinding of participants and personnel (performance bias) All outcomes	High risk	Comment: the study is open-label and blinding was not performed
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Insufficient information to make judgment, however it is unlikely
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quotes: "In the intention-to-treat analysis, all randomised patients who received at least one dose of the study drug and were subjected to the baseline evaluation were considered for the analysis." and "Outcome measures were analysed in all randomised patients who had taken at least one dose of the study medication (intention-to-treat population)..."

Ardizzone 2004 (Continued)

		Comment: ITT analysis applied, all withdrawals were low and balanced across groups
Selective reporting (reporting bias)	Low risk	Trial registration not available, however all outcomes stated in the method section assessed and reported
Other bias	Low risk	Quote: "No significant differences were observed between the 2 treatment groups regarding age, sex, duration of disease, location of disease, fistula and abscess at surgery, surgical procedure, previous operations, and CD therapy during the previous 6 months" Comment: baseline characteristics well balanced across groups

Armuzzi 2013

Methods	Study design: RCT, single centre Setting: Italy, 2007 to 2011
Participants	Inclusion: Consecutive CD participants who underwent curative ileocolonic resection (all macroscopically inflamed tissues were removed and operative margins were disease-free at histopathology examination) and considered at "high risk"* of postoperative recurrence were enrolled Exclusion: active perianal disease, presence of stoma, adverse events during previous therapy with infliximab or azathioprine, age > 70 years, surgical complications, active infectious diseases, history of cancer, renal, cardiac or hepatic failure, history of acute or chronic pancreatitis, severe leucopenia (WBC <3000 μ u/ml, lymphocyte count <1000 μ u/ml) and pregnancy Age (IG1 / IG2) median (range): 32 years (18 to 70 years) Sex (M:F): 15:7 overall; (7:4) versus (8:3) Type of surgery: Not reported Previous surgery (IG1+IG2): Not reported Start of intervention after surgery: 2 to 4 weeks Medication use (IG1+ IG2): Previous treatment with AZA-5; previous treatment with INF -10 Smoker (IG1 / IG2): Not reported Number randomised (N = 22): 11/11 Number analysed (N = 22): (11/11) versus (11/11) Post-randomisation exclusion (n = 0)
Interventions	Group 1: Infliximab (5 mg/kg) at 0, 2 and 6 week and then every 8 weeks for 1 year Group 2: Azathioprine (2.5 mg/kg/day) for 1 year All participants: All participants also received oral metronidazole (500 mg twice daily)

	for 2 weeks after surgery. No other CD-related drugs were admitted during the study. Participants were monthly evaluated, according to laboratory tests, the Harvey-Bradshaw Index (HBI) calculation and the adverse event report	
Outcomes	Duration of study: 12 months and follow-up at 40 months 1. Clinical recurrence defined by a HBI ≥ 8 2. Endoscopic recurrence defined by a Rutgeerts' score $\geq i2$ at 12 months and 40 months (follow-up) 3. Histologic activity score based on a Histology Score System modified from Regueiro et al 4. Adverse events	
Notes	Funding source: Not reported Conflict of interest: Authors declare the following conflict of interest: AA received: consultancy from Abbvie, MSD; lecture fees from Abbvie, MSD, Chiesi, Ferring, Nycomed, Otsuka; educational grants from Abbvie, MSD, Ferring, Nycomed. LG received: educational grants from Abbvie, MSD. CF, AP, MM, DP, GA, FF, IDV, GLR: nothing to declare Power calculation: Not reported	
<i>Risk of bias</i>		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "Subjects were randomised with a simple unblinded 1:1 allocation ratio to receive..." Comment: simple randomisation performed, however insufficient information on the method of randomisation used
Allocation concealment (selection bias)	Unclear risk	Not stated
Blinding of participants and personnel (performance bias) All outcomes	High risk	Open-label study design
Blinding of outcome assessment (detection bias) All outcomes	High risk	Quote: "One unblinded endoscopist (AP) did all the examinations and calculated scores. Two further unblinded endoscopists (IDV and GA) separately reviewed videos and in case of discordance a consensus agreement was reached among the three operators" Comment: blinding of outcome assessors not performed

Armuzzi 2013 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "One patient did not tolerate azathioprine because of severe nausea with epigastric pain and withdrew from the study after 5 weeks of treatment" Comment: only one patient withdrew from the study and reason described
Selective reporting (reporting bias)	Low risk	Trial registration not available, however all outcome data stated in the method section were reported
Other bias	Low risk	Groups well balanced at baseline and no other apparent sources of bias detected

D'Haens 2008

Methods	Study design: RCT, multicentre Setting: Belgium / University Hospital Leuven and Imelda General Hospital, Bonheiden; 1999 to 2005	
Participants	<p>Inclusion: Adult participants (18 to 70 years) who underwent curative ileal or ileocolonic resection with ileocolonic anastomosis for CD with a presence of 1 risk factor for the development of early/severe postoperative recurrence of their CD. Participants had to understand and sign a written informed consent form. Women of childbearing age needed to have a negative pregnancy test and had to use adequate birth control measures during the whole study</p> <p>Exclusion: Presence of macroscopic evidence for CD proximally or distally to the site of resection or the presence of frank pancolitis or an ileorectal anastomosis (ileosigmoidal anastomosis was allowed); participants with a stoma; operation for fibrostenosis only, without evidence of inflammatory activity on histology; former intolerance to metronidazole and/or AZA; who wished to become pregnant; low white blood cell count at inclusion (4000); alcohol or drug abuse; participants who had used AZA in the 2 months before surgery; participants with malignancies and/or ongoing infectious disease (hepatitis, tuberculosis, AIDS) with the exception of herpes simplex infection. Former use of biologicals was not permitted</p> <p>Age (IG1 / IG2) mean: 38.8 years (22 to 67 years) versus 40.0 years (21 to 69 years); overall age not reported</p> <p>Sex (M:F): 44:37 overall; (24:16) versus (20:21)</p> <p>Type of surgery: Not reported</p> <p>Previous surgery (IG1+IG2): Second surgery-20 (12/8); third surgery-3 (2/1)</p> <p>Start of intervention after surgery: ≤ 2 weeks</p> <p>Medication use (IG1+ IG2): AZA past use: 5 (3/2); Steroid use at surgery: 21 (12/9)</p> <p>Smoker (IG1 / IG2): (13/40) versus (17/41)</p> <p>Number randomised (N = 81): 40/41</p> <p>Number analysed (N = 81): (40/40) versus (41/41)</p> <p>Post-randomisation exclusion (n = 5): (3/40) versus (2/41) (Withdrawal of consent-5 (3/2))</p>	

Interventions	<p>Group 1: 3 months of metronidazole therapy at a dose of 250 mg 3 times per day plus AZA depending on body weight. AZA only for the rest of the study. Participants whose body weight was 60 kg received 2 tablets of AZA (100 mg), whereas participants weighing 60 kg received 3 tablets or 150 mg AZA</p> <p>Group 2: 3 months of metronidazole therapy at a dose of 250 mg 3 times per day plus placebo. Placebo only for the rest of the study</p> <p>All participants: Participants intolerant to metronidazole were switched to ornidazole 500 mg twice per day orally. All concomitant anti-inflammatory medications were discontinued, except for glucocorticosteroids, which were gradually tapered over 6 weeks after surgery. Antibiotics were allowed during the study for concurrent infections, but not for CD. Topical therapy for perianal CD could be continued if necessary. Cholestyramine was allowed for the treatment of bile acid diarrhoea. Participantswere instructed to take their other drugs at least 1 hour after the intake of cholestyramine. Participants underwent clinical evaluation with physical examination and biochemical analysis at baseline and weeks 2, 6, 12, 20, 28, 36, 44, and 52 after randomisation. At week 12 and 52, participants underwent an ileocolonoscopy. Adverse events and concomitant medication were recorded at every scheduled or unscheduled visit.</p>	
Outcomes	<p>Duration of study: 12 months</p> <p>1. Endoscopic recurrence in the neoterminal ileum defined as an endoscopic index ≥ 2 according to Rutgeerts' endoscopic score</p> <p>2. Clinical recurrence defined as CDAI > 250</p> <p>3. Adverse events</p> <p>4. Withdrawal due to adverse events</p>	
Notes	<p>Funding source: Not reported</p> <p>Conflict of interest: Not reported</p> <p>Power calculation: It was estimated on the basis of prior recurrence-prevention studies, that 50-55% of the participants in the placebo group would have endoscopic recurrence at 1 year. Assuming an efficacy of 65% of AZA, it was calculated that 80 participants were needed to be enrolled in the trial to detect differences in significant endoscopic recurrence among the groups</p>	
<i>Risk of bias</i>		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "The random allocation sequence was delivered by a randomisation program written in Visual Basic version 6" Comment: Computer generated randomisation
Allocation concealment (selection bias)	Unclear risk	Quote: "Randomization took place in the pharmacy of the Leuven University Hospitals within 2 weeks after surgery" Comment: insufficient information to make judgment

D'Haens 2008 (Continued)

Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Unclear if placebo identical to active drug
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "At week 12 and 52, an ileo-colonoscopy was performed with determination of Rutgeerts' score for ileal recurrence of CD by an endoscopist who was unaware of treatment assignment" Comment: Probably done
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "Both intention-to treat and per-protocol analyses were performed" Comment: ITT analysis applied and attrition rates were similarly low across groups
Selective reporting (reporting bias)	Low risk	Trial registration not available, however, all outcomes stated in the method section adequately reported
Other bias	Low risk	Quote: "The characteristics of the study populations in the AZA and placebo group were comparable" Comment: Groups well balanced at baseline, no other apparent sources of bias detected

Hanauer 2004

Methods	Study design: RCT, multicentre Setting: USA and Belgium / 5 centres; 1992 to 1996
Participants	Inclusion: Participants 18 to 65 years of age, with diagnosis of CD for at least 6 months and scheduled for curative ileo-caecal resection; ability to start oral nutrition within 7 days of operation, need for curative ileo-caecal resection, and resection margins free of inflammation Exclusion: Active perianal disease or any active disease in other segments of the intestine, anti-TNF- α , and/or investigational treatment within 4 months prior to surgery; current treatment with 5-ASA, azathioprine/6MP, or methotrexate; bowel surgery performed less than 3 months previously; history of colostomy or ileostomy; infections, neoplasia, or uncontrolled diseases; or anticipation of noncompliance with protocols. Subjects who were receiving steroids preoperatively were tapered and weaned according to a strict schedule Age (IG1 / IG2) mean (SD): 34.4 \pm 11.0 years overall; 34.9 \pm 11.5 years versus 34.1 \pm 10.9 years versus 34.2 \pm 10.9 years Sex (M:F): 60:71 overall; (23:24) versus (19:25) versus (18:22) Type of surgery: Not reported Previous surgery (IG1+IG2): 18 (7/11)

	Start of intervention after surgery: Therapy initiated before postoperative hospital discharge Medication use (IG1+ IG2): Not reported Smoker (IG1 / IG2): Not reported Number randomised (N = 131): 47/44/40 Number analysed (N = 131): (47/131) versus (44/131) versus (40/131) Post-randomisation exclusion (n = 27): (12/47) versus (7/44) versus (8/40) (Withdrawn consent-5 (1/2/2); Surgical complication-3 (2/0/1); Noncompliance-9 (2/4/3); Lost to follow-up-10 (4/2/4))	
Interventions	Group 1: 50 mg of 6-mercaptopurine (Purinethol) once daily Group 2: 3 g of Mesalamine (Pentasa); 4 capsules of 250 mg, 3 times daily Group 3: Identical matching placebo All participants: Presurgical therapy, including aminosaliclates, antibiotics, or immunomodulators, was discontinued before surgical resection and was not allowed during the postoperative trial. Preoperative treatment with corticosteroids was completely tapered by 3 months after hospital discharge at a rate determined by the treating physician. No concurrent treatment for Crohn’s disease, aside from topical therapy for perianal disease, was allowed during the duration of the trial. Continuous use of nonsteroidal anti-inflammatory drugs was not allowed during the study. If the white blood cell count and platelet counts fell below 4500/L or 150,000/L, respectively, the dosage of 6-MP was reduced by one half	
Outcomes	Duration of study: 24 months 1. Endoscopic recurrence defined as i≥1 according to the Rutgeerts scoring system: i1-i2 mild to moderate; i3-i4 severe. Relapse defined as i≥1 2. Clinical recurrence defined as CDAI > 150 points or an increase in CDAI score of > 70 points or higher from baseline 3. Histological score assessed by the Geboes scoring system 4. Adverse events 5. Serious adverse events 6. Withdrawal due to adverse events	
Notes	Funding source: Not reported; However, authors contacted by email on 02/08/2018 and declared none Conflict of interest: Not reported; However, authors contacted by email on 02/08/2018 stating that study was funded by Crohn’s and Colitis Foundation Power calculation: Sample size calculations were performed for the endoscopic criteria, using 2-sided of 0.05 and 80% power, based on a predicted endoscopic recurrence of 75% at 1 year in the placebo group. A sample size of 50 in each group allows sufficient power to detect a 40% reduction in mild Crohn’s disease lesions and a 75% reduction in more severe lesions at 1 year	
<i>Risk of bias</i>		
Bias	Authors’ judgement	Support for judgement

Random sequence generation (selection bias)	Low risk	<p>Quotes: Patients were randomised by a central computer by permuted blocks of 6 (unknown to investigators) per centre to receive mesalamine (Pentasa; Marion Merrell Dow, Kansas City, MO) 3 g daily, 6-MP (Purinethol; Burroughs Wellcome, Research Triangle Park, NC) 50 mg daily, or placebo</p> <p>Comment: Computer generated random sequence</p>
Allocation concealment (selection bias)	Low risk	<p>Quotes: "Medications were prepared and dispensed by an assigned pharmacist at each site's investigational pharmacy who was not directly involved in the care of the patients"</p> <p>Comment: Treatment controlled by pharmacies at each centre</p>
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	<p>Quotes: "Medications were prepared and dispensed by an assigned pharmacist at each site's investigational pharmacy who was not directly involved in the care of the patients" and "An evaluating (treating) physician followed up each patient and was blinded as to the study drug and laboratory results"</p> <p>Comment: Placebo-controlled, double-blind RCT. However, it is unclear whether both study drugs were sufficiently identical with the placebo to blind study participants</p>
Blinding of outcome assessment (detection bias) All outcomes	Low risk	<p>Quotes: "Patient evaluation consisted of assessments of clinical, endoscopic, and radiographic disease activity at each study site by the blinded physician" and "Colonoscopic examinations with endoscopic descriptions and photography of the anastomosis and pre-anastomotic ileum were performed by the blinded investigators (all gastroenterologists) at months 6, 12, and 24" and "Radiographic interpretations were performed by the blinded inflammatory bowel disease radiologist at each institution"</p> <p>Comment: Assessors blinded to treatment</p>
Incomplete outcome data (attrition bias) All outcomes	Low risk	<p>Quotes: "The clinical recurrence rates were determined using ITT"</p> <p>Comment: ITT analysis applied, attrition low, similar and balanced across groups</p>

Hanauer 2004 (Continued)

Selective reporting (reporting bias)	Low risk	Comment: All outcomes stated in the method section reported
Other bias	Low risk	Quote: "There were no statistical differences in patient age, sex, disease duration, indications for surgical resection, or preoperative disease activity among the 3 groups" Comment: Groups well balanced at baseline. No other apparent sources of bias detected

Herfarth 2006

Methods	Study design: Multicentre RCT Setting: Not stated (multicentre RCT)
Participants	Inclusion: People with Crohn's who had undergone resective surgery Exclusion: Homozygous TPMT Age: Not reported Sex: Not reported Type of surgery: Not reported Previous surgery: Not reported Start of intervention after surgery: within 2 weeks postoperative Medication use (IG1+ IG2): Smoker (IG1 / IG2): Not reported Number randomised (N = 79): 42/37 Number analysed (N = 37): 18/19 Post-randomisation exclusion (n = 42)
Interventions	Group 1: 2.0 to 2.5 mg/kg body weight/day azathioprine Group 2: 4 g 5-ASA/day All participants: Not stated
Outcomes	Duration of study: 1 year (study was discontinued after one year) 1. Treatment failure (due to severe endoscopic recurrence, lack of efficacy and AE related to study drug) 2. Clinical or severe endoscopic relapse 3. Severe endoscopic relapse 4. Clinical relapse (reviewer calculated: clinical or severe endoscopic relapse minus severe endoscopic relapse) 5. Adverse events 6. Withdrawal due to adverse events
Notes	Funding source: Dr. Falk Pharma GmbH, Freiburg, Germany Conflict of interest: Not reported Power calculation: Not reported
Risk of bias	

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	<p>"Patients in the present study were assigned to one of the two treatment groups (5-ASA or azathioprine) at random</p> <p>For creation of the randomisation list the programme "Rancode +" (version 3.6) of IDV, Gauting (Germany) was used. The randomisation into two treatment groups was performed in blocks of four. After voluntary written informed consent was obtained and basic selection criteria were checked, the investigator requested the allocation of a unique patient code number (randomisation number, consecutively allocated to each patient), and received medication packs with the randomisation number for the patient"</p> <p>Comment: Confirmed by correspondence from Muller R (2/5/2012)</p>
Allocation concealment (selection bias)	Low risk	<p>"The randomization code was prepared and stored by a statistician from a CRO, who was not involved in the conduct nor in the analysis of the study. The Qualified Person of the Sponsor and the contract manufacturer responsible for the preparation of the double-dummy patients sets received a copy of the randomization list, which was safely stored at both sites, without allowing access by other people. Neither the investigator nor the study team from the clinical operation from the sponsor nor the CRO had access to the random list"</p> <p>Comment: Confirmed by correspondence from Muller R (2/5/2012)</p>
Blinding of participants and personnel (performance bias) All outcomes	Low risk	<p>"This was a double-blind, double-dummy study. Patients randomized to administer 5-ASA had to take 5-ASA VERUM tablets AND azathioprine PLACEBO tablets. Patients randomized to receive azathioprine had to administer azathioprine VERUM tablets AND 5-ASA PLACEBO tablets</p> <p>Therefore, neither the investigator, nor the patients, nor the sponsor were ware of the TX a patient received until the database was clean, closed, and the code was broken"</p>

Herfarth 2006 (Continued)

		Comment: Confirmed by correspondence from Muller R (2/5/2012)
Blinding of outcome assessment (detection bias) All outcomes	Low risk	“This was a double-blind, double-dummy study. Patients randomized to administer 5-ASA had to take 5-ASA VERUM tablets AND azathioprine PLACEBO tablets. Patients randomized to receive azathioprine had to administer azathioprine VERUM tablets AND 5-ASA PLACEBO tablets Therefore, neither the investigator, nor the patients, nor the sponsor were aware of the TX a patient received until the database was clean, closed, and the code was broken” Comment: Confirmed by correspondence from Muller R (2/5/2012)
Incomplete outcome data (attrition bias) All outcomes	High risk	Quote: “The study was stopped prematurely after an interim-analysis due to a high therapy failure rate. 38 patients (AZA 18 patients; 5-ASA 20 patients) completed the study and could be evaluated regarding the primary endpoint therapy failure. The other patient terminated the trial prematurely due to the study stop, but were also evaluated for adverse events (AE) and adverse drug reactions (ADR)” Comment: 51% of randomised participants discontinued. High risk for primary outcome and low risk for AE and withdrawal due to AE
Selective reporting (reporting bias)	Unclear risk	Insufficient information as trial registration was not available and study was published as abstract
Other bias	Unclear risk	Insufficient information as study was published as abstract

Lopez-Sanroman 2017

Methods	Study design: RCT, multicentre Setting: Spain, 22 centres; 2012 to 2015
Participants	Inclusion: Adults (18-70 years) who underwent a resective surgical procedure (radical or non-radical) for a CD-specific lesion at 1 of the participating centres; diagnosis of CD established by generally accepted endoscopic, histological, and/or radiological criteria at least 6 months before surgery; evaluation of disease location by a complete investigation of the gastrointestinal tract (gastroscopy, colonoscopy, and small

	<p>bowel radiography) within a maximum of 1 year before the index surgery; and ability to start oral nutrition (and, thus, oral medication) within the first 10 postoperative days</p> <p>Exclusion: Contraindications for use of mesalamine; pregnancy or intention of pregnancy within the next 18 months; nursing; short bowel syndrome; clinically significant lactase deficiency; any severe additional disease; diagnosis of primary sclerosing cholangitis; presence of an ileocolonic stoma; more than 3 surgeries preceding the index surgery; and failure to obtain informed consent</p> <p>Age (IG1 / IG2) median [interquartile range]: overall age not reported; 37.00 years [31.00 to 47.00 years] versus 35.00 years [30.0 to 40.0 years]</p> <p>Sex (M:F): 42:42 overall; (23:16) versus (19/26)</p> <p>Type of surgery: not reported</p> <p>Previous surgery (IG1+IG2): 6 (3/3)</p> <p>Start of intervention after surgery: after surgery (consent obtained before surgery)</p> <p>Medication use (IG1+ IG2): Glucocorticoids-80 (38/42); Immunosuppressants [thiopurines or methotrexate]-63 (28/35); Anti-TNF-α - 49 (21/28)</p> <p>Smoker (IG1 / IG2): 20 (9/11)</p> <p>Number randomised (N = 85): 40/45</p> <p>Number analysed (N = 84): (39/40) versus (40/40)</p> <p>Post-randomisation exclusion (n = 3): (1/40) versus (2/45) Consent withdrawal before treatment-1 (0/1); Loss to follow-up -2 (1/1)</p>
Interventions	<p>Group 1: AZA 2.5 mg/kg/day for one year + Metronidazole 250 mg three times a day by mouth was added for the first 3 months</p> <p>Group 2: ADA 160 mg subcutaneously, then 80 mg at Week 2, or 40 mg at Week 4 and every 2 weeks thereafter for one year + Metronidazole 250 mg three times a day by mouth was added for the first 3 months</p> <p>All participants: Adherence to therapy was assessed by direct questioning and by counting of returned medication</p>
Outcomes	<p>Duration of study: 52 weeks</p> <p>1. Endoscopic recurrence defined as $i \geq 2$, 3 and 4 based on Rutgeerts score (24 and 52 weeks)</p> <p>2. Clinical recurrence defined by 1 of the following: increase in CDAI above 200 (24 and 52 weeks) (CDAI ≥ 200: derived from number randomised - remissions)</p> <p>3. Radiologic recurrence rate</p> <p>4. Health Related Quality of Life</p> <p>5. Adverse events</p> <p>6. Serious adverse events</p> <p>7. Withdrawal due to adverse events</p>
Notes	<p>Funding source: unrestricted grant from AbbVie [Spanish Working Group on Crohn's Disease and Ulcerative Colitis] The funding group had no role in the study design, data collection, data analysis, data interpretation, writing of the report, or decisions concerning publication. The authors had unrestricted access to the data; the decision to submit the paper for publication was solely and entirely to theirs</p> <p>Conflict of interest: All authors have declared conflict of interest (mainly grants, personal fees, collaboration with AbbVie outside the submitted work, research funding from AbbVie etc.)</p> <p>Power calculation: The difference in the proportion of endoscopic recurrence between</p>

	treatment groups was estimated at 35% (10% for ADA + metronidazole and 45% for AZA + metronidazole), considering a type 1 error of 5%, a two-tailed contrast with Yates' continuity correction, 90% power (1-type II error), and an allocation ratio of 1:1. Therefore, 38 participants per treatment group would be needed. Withdrawals were estimated at 10%. The minimal sample was estimat3d at 84 evaluable participants.	
Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote:“Central randomisation was based on a pre-generated block randomisation list stratified by centre.” and “Patients were assigned [1:1] to..” Comment:Central randomisation
Allocation concealment (selection bias)	Low risk	Quote:“Central randomisation was based on a pre-generated block randomisation list stratified by centre...Allocation was concealed by means of a computer-generated randomisation schedule without stratification or block allocation”
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote:“Neither patients nor investigators were blinded to the administered treatment” Comment: No blinding of personnel and participants performed
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote:“A video recording of the last 15 cm of the neo-terminal ileum was evaluated by an endoscopist blinded to treatment allocation and experienced in application of the Rutgeerts score [VP]” and “..MRE, which was evaluated centrally by an experienced blinded reader [JR];” Comment:Outcome assessors we blinded to treatment
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote:“We defined the following populations: 1] the intention-to-treat [ITT] population, which included all consenting patients who were randomised and received at least one dose of the study medications” Comment: ITT analysis applied, reasons for withdrawal reported and attrition rates were balanced across groups

Selective reporting (reporting bias)	High risk	Trial registration was available (NCT01564823) and all prespecified outcomes were reported in the study except health related quality of life which was only reported as a P-value in an abstract
Other bias	Low risk	Quote: "The groups were similar regarding baseline characteristics, including smoking status, previous resections, CD phenotype, previous perianal disease, and previous drug exposure" Comment: Groups well balanced at baseline. No other apparent sources of bias detected

Mowat 2016

Methods	Study design: RCT, multicentre, Setting: UK / 29 secondary and tertiary hospital; 2008 to 2012
Participants	<p>Inclusion: Participants aged at least 16 years (Scotland) or 18 years (England and Wales) who had a diagnosis of Crohn's disease and an ileocolic or small bowel resection within the preceding 3 months were eligible for inclusion. Patients successfully treated for a malignancy and in remission for at least 5 years were also eligible</p> <p>Exclusion: Residual active Crohn's disease present after surgery, known intolerance or hypersensitivity to thiopurines, known need for further surgery, stricturoplasty alone, formation of a stoma, active or untreated malignancy, absent thiopurine methyltransferase activity, substantial abnormalities of liver function tests or full blood count, and pregnancy. Patients receiving treatment for active Crohn's disease at random allocation</p> <p>Age (IG1 / IG2) mean (SD): 38.76 ± 13.1 years overall; 39.2 ± 12.08 years versus 38.21 ± 13.4 years</p> <p>Type of surgery: not reported</p> <p>Previous surgery (IG1+IG2): not reported</p> <p>Start of intervention after surgery: ≤ 3 months</p> <p>Medication use (IG1+ IG2): not reported</p> <p>Smoker (IG1 / IG2): not reported</p> <p>Number randomised (N = 240): 128/112</p> <p>Number analysed (N = 240): (128/128) versus (112/112)</p> <p>Post-randomisation exclusion (n = 56): abnormal blood test results-18 (12/6); early withdrawal - 21 (8/13); loss to follow-up - 16 (8/7); death-1 (0/1)</p>
Interventions	<p>Group 1: Once daily oral 6-mercaptopurine, at a dose of 1 mg/kg bodyweight rounded to the nearest 25 mg. Patients with low thiopurine methyltransferase activity were prescribed half the normal dose for 3 years</p> <p>Group 2: Identical matched placebo for 3 years</p> <p>All participants: Blood monitoring was done weekly for the first 6 weeks and thereafter at 6-weekly intervals. Patients with abnormal results had a dose reduction, temporary</p>

	cessation, or cessation as per a study algorithm. At each study visit, the following data were collected: CDAI, physical examination, concomitant medications, and patient-reported outcomes, including the IBDQ	
Outcomes	Duration of study: 3 years 1. Clinical recurrence defined as CDAI score of over 150 and a 100-point increase from baseline, and the need for anti-inflammatory rescue treatment or primary surgical intervention 2. Secondary endpoint of clinical recurrence defined as reaching either of the individual components of the primary outcome (i.e. either a CDAI score of >150 and a 100-point increase from baseline, or the need for anti-inflammatory rescue treatment or primary surgical intervention) 3. Endoscopic relapse defined as a Rutgeerts score of ≥ 2 4. Crohn's Disease Endoscopic Index of Severity 5. Health-related quality of life 6. Adverse events 7. Severe adverse events 8. Withdrawal due to adverse events	
Notes	Funding source: Funded by the Efficacy and Mechanism Evaluation programme, a Medical Research Council and National Institute for Health Research (NIHR) partnership. They had no role in study design, data collection, data analysis, data interpretation, or writing of the report Conflict of interest: Authors declare none conflicting interests Power calculation: A sample size of 234 patients was needed to give 80% power to detect a reduction in the frequency of recurrence from 50% in the placebo group to 30% in the treatment group by 3 years at the 5% level of significance	
<i>Risk of bias</i>		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "Patients were randomly assigned (1:1) to mercaptopurine or identical matched placebo using a computer-generated web-based randomisation system managed by the Edinburgh Clinical Trials Unit (University of Edinburgh, Edinburgh, UK) Comment: computer-generated web-based random sequence
Allocation concealment (selection bias)	Low risk	Quote: "Patients' details were entered into the randomisation system before random allocation and were concealed at randomisation" Comment: Web-based central allocation

Mowat 2016 (Continued)

Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "Patients and their carers and physicians were masked to the treatment allocation" Comment: The study is placebo-controlled
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "Blood monitoring results were reviewed by an independent central clinician masked to treatment allocation and to mean corpuscular volume results. To protect masking, investigators were informed that sham dose reductions were planned for patients on placebo. However, on the advice of the data monitoring committee, sham dose reductions did not occur; the investigators were not informed of this" Comment: Outcome assessors were blinded to treatment
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "Analyses were by intention to treat" Comment: ITT analysis applied. Overall attrition rate of 23% when compared with the event risk (30%), was not considered sufficient to lead to bias
Selective reporting (reporting bias)	Low risk	Trial registration available (ISRCTN89489788) and all outcomes stated in the method section reported
Other bias	Low risk	Quote: "Baseline characteristics were similar between study groups" Comment: Groups well balanced at baseline. No other apparent sources of bias detected

Reinisch 2010

Methods	Study design: RCT, multicentre Setting: Austria, the Czech Republic, Germany and Israel ; 21 centres, 2002 to 2007
Participants	Inclusion: Male or female patients aged 18-70 years with a diagnosis of CD confirmed by endoscopy and histology were eligible for screening if they had (1) undergone resection of the terminal ileum and partial colectomy with ileocolonic resection for complications of ileal CD with construction of an ileocolonic anastomosis in the preceding 6-24 months; (2) not experienced clinical recurrence due to CD since resection; and (3) a Crohn's disease activity index (CDAI) score <200 in the preceding 1-2 weeks. Patients with moderate endoscopic recurrence (Rutgeerts grade i2a: >5 aphthous lesions with normal mucosa between the lesions, or skip areas of larger lesions) or severe endoscopic recurrence

	<p>(i3-i4: diffuse aphthous ileitis with diffusely inflamed mucosa, or diffuse inflammation with larger ulcers, nodules and/or narrowing) were recruited into the study</p> <p>Exclusion: Patients with a short bowel syndrome, an ileocolonic stoma, a thiopurine methyltransferase genotype, patients who had received treatment with immunosuppressant agents (methotrexate, ciclosporin, 6-MP, azathioprine or 6-thioguanine (6-TG) or anti-tumour necrosis factor α (TFNα) since resection, corticosteroids or oral antibiotics (e.g. metronidazole or ciprofloxacin) for >4 weeks since resection, non-steroidal anti-inflammatory drugs (NSAIDs) within the preceding 2 weeks (other than paracetamol or low-dose acetylsalicylic acid); patients who currently had stricturoplasty (unless the present stricture plasty macroscopically showed no inflammation at the time of the index operation) or had serum creatinine >130 μmol/l. Patients were excluded if endoscopy revealed no lesions (grade i0), <5 aphthous lesions (grade i1) and/or if lesions were confined to the ileocolonic anastomosis (i.e. <1 cm long) (grade i2b). Patients in the latter category (grade i2b) were excluded since this presentation is associated with a lower risk of clinical recurrence</p> <p>Age (IG1 / IG2) mean: 35.8 \pm 12.08 years overall; 35.5 \pm 13.6 years versus 36.0 \pm 10.7 years</p> <p>Sex (M:F): 44: 34 overall; (24:17) versus (20/17)</p> <p>Type of surgery: not reported</p> <p>Previous surgery (IG1+IG2): 1 or 2 surgeries-114 (63/51)); >2 surgeries -12 (4/8)</p> <p>Start of intervention after surgery: 6 to 24 months</p> <p>Medication use (IG1+ IG2): Mesalazine - 54 (28/26); Sulfasalazine- 5 (4/1); Budesonide- 22 (9/13); Corticosteroids- 39 (23/16); Azathioprine- 14 (6/8); Infliximab-3 (2/1); Other - 12 (6/6)</p> <p>Smoker (IG1 / IG2): 37 (17/20)</p> <p>Number randomised (N = 78): 41/37</p> <p>Number analysed (N = 78): (41/41) versus (37/37)</p> <p>Post-randomisation exclusion (n = 9): (4/41) versus (5/37) ; Lack of cooperation-7 (4/3); lack of efficacy-2 (0/2)</p>
Interventions	<p>Group 1: Azathioprine 2.0 - 2.5 mg/kg/day (Azafalk 50 mg tablets) + placebo mesalazine tablets</p> <p>Group 2: Mesalazine 4 g/ day (Eudragit L-coated 500 mg tablets (Salofalk)) + placebo azathioprine tablets</p> <p>All participants: Medications prohibited during the study: immunosuppressants other than study drug, allopurinol, oxipurinol or thiopurinol, azathioprine-containing or mesalazine containing drugs other than study drug, anti-TNF-α therapy, oral antibiotics for >4 weeks or more than three cycles of 2 weeks, NSAIDs for >2 weeks, corticosteroids and cimetidine</p>
Outcomes	<p>Duration of study: 52 weeks</p> <ol style="list-style-type: none"> 1. Therapeutic failure (Clinical relapse) defined as CDAI score \geq 200 and an increase of \geq 60 points from baseline or study drug discontinuation due to lack of efficacy or an intolerable adverse drug reaction 2. Endoscopic recurrence defined by endoscopic Rutgeerts score \geq i2 only 3. Health-related quality of life based on IBDQ score at 12 months 4. Adverse events 5. Clinical recurrence follow-up defined as a Rutgeerts score between i2-i4 within 24 months after the 1-year treatment

Notes	<p>Funding source: Dr Falk Pharma GmbH, Freiburg, Germany</p> <p>Conflict of interest: WR has received an unrestricted grant from Dr. Falk Pharma. EFS and KRH have received speaker's honoraria. KD, RG and RM are employees of Dr. Falk Pharma. SA, WP, OS, ML, SB-M, AT, ES and MS have no conflicts of interest to declare. In part, AT, ES and MS are supported by the Robert Bosch Foundation, Stuttgart, Germany</p> <p>Power calculation: The sample size calculation for the primary end point estimated that 62 evaluable patients (31 per treatment arm) were needed to have 80% power to detect a difference of 35% in favour of azathioprine versus mesalazine for the reduction in the 1 year therapeutic failure rate (one-sided $\alpha=0.025$). To allow for non-evaluable patients, a population size of 76 patients (38 per treatment arm) was planned</p>
-------	---

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "...a central randomisation was performed via five computer-generated randomisation lists (using the program 'Ran-code +' (version 3.6) of IDV, Gauting, Germany), which were generated for the five body weight classes (40-50 kg, 51-60 kg, 61-75 kg, 76-100 kg and 101-128 kg), each in blocks of four, with medication distributed to each centre according to this list" Comment: Computer-generated randomisation
Allocation concealment (selection bias)	Low risk	Centralized randomisation in blocks of 4
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "To maintain investigator and patient blinding, patients randomised to azathioprine received verum azathioprine tablets and placebo mesalazine tablets; those randomised to mesalazine received verum mesalazine tablets and placebo azathioprine tablets" Comment: a double-blind, double-dummy RCT
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Insufficient information to make judgement
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "The intention-to-treat (ITT) population was defined as all randomised patients who received 1 dose of study medication"

		Comment: The intention-to-treat (ITT) population was defined as all randomised patients who received 1 dose of study medication
Selective reporting (reporting bias)	Low risk	Trial registration available (NCT00946946) and all prespecified outcomes were reported
Other bias	Low risk	Quote: "Baseline characteristics were similar between treatment groups apart from a lower mean CDAI value in the azathioprine cohort (70 versus 102 in the mesalazine arm) and a higher proportion of azathioprine patients with a penetrating disease behaviour (66% versus 43%)" Comment: Some differences at baseline; study supported by Falk Pharma but conflict of interest declared. No other apparent sources of bias detected

Savarino 2013

Methods	Study design: RCT, single Setting: Italy; University Hospital of Genoa; 2008 to 2010
Participants	Inclusion: Adult patients with ileal or ileocolonic CD within 4 weeks of resection of macroscopically diseased bowel with anastomosis between normal ileum and colon Exclusion: Patients with (i) more than 10 years of CD requiring first resective surgery for short (10 cm) fibrostenotic stricture, (ii) macroscopically active disease not resected at the time of surgery, and (iii) presence of a stoma Age (IG1 / IG2) median (range): not reported, overall > 18 years; 45 (22 to 66 years) versus 46 (25 to 65 years) Sex (M:F): 25:26 overall; (8:8) versus (9:8) versus (8:10) Type of surgery: not reported Previous surgery (IG1+IG2): one-40 (12/15/13); two-9 (3/2/4); three-2 (1/0/1) Start of intervention after surgery: 2 to 4 weeks Medication use (IG1+ IG2): Not reported Smoker (IG1 / IG2): 19 (9/4/6) Number randomised (N = 51): 16/17/18 Number analysed (N = 51): (16) versus (17) versus (18) Post-randomisation exclusion (n = 5): (1/16) versus (2/17) versus (2/18) (unclear)
Interventions	Group 1: Adalimumab subcutaneous injections 160 / 80 mg at 0 and 2 weeks, followed by 40 mg every 2 weeks for 2 years Group 2: Azathioprine (Azafor, Sofar S.P.A., Milan, Italy), at the dose of 2 mg / kg every day for 2 years Group 3: Mesalamine (Pentasa, Ferring S.P.A., Milan, Italy), at the dose of 3 g / day divided in 3 doses for 2 years

	All participants: Patients on antibiotics or immunomodulators at entry into the study discontinued these medications 12 weeks before surgery. Continuous use of nonsteroidal anti-inflammatory drugs was not allowed during the study. No other medications were prescribed except for occasional tablets of paracetamol or tramadol. Patients were subjected to endoscopy at 12 and 24 months; small bowel enteroclysis or magnetic resonance imaging at 12 and 24 months; physical examination with interviews, together with an extensive battery of blood tests weekly for the first 4 weeks and then every 2 months, and completed an IBD-Q at 1 month before surgery and at 12 and 24 months after surgery. The CDAI was determined at each study visit. In addition, adverse events were ascertained at each visit	
Outcomes	Duration of study: 2 years 1. Clinical recurrence defined as a score of ≥ 2 on the clinical recurrence grading scale 1-4 proposed by Hanauer et al 2. Clinical recurrence based on CD activity index (CDAI) was calculated for each patient and recurrence was set in case of a score > 200 , whereas clinical remission was defined by a CDAI score of < 150 2. Endoscopic recurrence defined by a Rutgeerts score of ≥ 2 3. Radiologic recurrence defined as a score of ≥ 2 on the radiographic recurrence grading scale (where 1 indicates normal; 2, mucosal edema / aphthoid ulcers; 3, linear ulcers / cobblestoning; and 4, strictures / fistulas / inflammatory mass) 4. Health-related quality of life 5. Median Lémann Index 5. Adverse events	
Notes	Funding source: supported by research funds of the university Conflict of interest: Authors declare no conflict of interest Power calculation: we considered reasonable to hypothesize an endoscopic recurrence rate of ~ 80 % and 15 % and a clinical recurrence rate of ~ 65 % and 5 % for the mesalamine and ADA groups, respectively, at 2 years of follow-up. This estimation has been supported by the results shown in previous trials on postoperative CD relapse. Thus, based on these data, 13 patients per treatment group resulted to be sufficient to detect a difference of at least 65 % for endoscopic recurrence and 60 % for clinical recurrence in favour of the ADA group with a power of 80 % (global type I error of 5 %). The number of patients in each group was increased to 16 to compensate for an anticipated dropout rate of 15 %	
<i>Risk of bias</i>		
Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "Eligible and consenting patients were assigned randomly using a computer-generated sequence (www.randomizer.org) to a regimen of..." Comment: Computer generated random sequence

Savarino 2013 (Continued)

Allocation concealment (selection bias)	Low risk	Quote: "Patient allocation was concealed and performed by an independent nurse not involved with the trial" Comment: Probably done
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study is open-label design
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Quote: "A blinded investigator (P.D.) reviewed each patient's video-recorded procedure and provided a separate endoscopic score" and "At the conclusion of the study, the principal investigator (E.S.) rescored each patient by re-reviewing the video recordings in a random and blinded manner" Comment: Assessors were blinded for endoscopic assessments only. However, no information on clinical assessment of relapse
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "Statistical analysis was conducted according to the intention-to-treat principle." Comment: ITT analysis applied. Withdrawals and reasons reported
Selective reporting (reporting bias)	Low risk	Trial registration not available, however, all outcomes stated in the method section reported
Other bias	Low risk	Quote: "Characteristics were similar for sex, age, smoking, duration of CD, disease behavior, disease location, prior medication exposure, including IFX, and prior surgical resection" Comment: Groups well balanced at baseline; no other apparent sources of bias detected

Scapa 2015

Methods	Study design: RCT; abstract Setting: Tel Aviv, Israel; study period not reported
Participants	Inclusion: All CD patients undergoing a first ileocectomy for inflammatory complications were prospectively recruited to the Post OPerative Adalimumab Recurrence Trial (POPART) Exclusion: Not reported

	Age (IG1 / IG2) median (SD): overall not reported; 30.5 ± 2.3 years versus 34.4 ± 2.5 years Sex (M:F): not reported Type of surgery: not reported Previous surgery (IG1+IG2): not reported Start of intervention after surgery: < 45 days Medication use (IG1+ IG2): Not reported Smoker (IG1 / IG2): 4 (1/3) Number randomised (N = 19) Number analysed (N = 19): (8) versus (11) Post-randomisation exclusion (n = ?)	
Interventions	Group 1: Thiopurine (6-mercaptopurine 1.5 mg/kg/day) Group 2: Adalimumab 160 mg/ 80 mg and then 40 mg every other week All participants: All patients underwent ileocolonoscopy at 6 and 12 months to asses for endoscopic recurrence as defined by the Rutgeert’s score	
Outcomes	Duration of study: 12 months 1. Endoscopic recurrence defined as a Rutgeert’s score of i0-i1, while advanced lesions were defined as i2 to i4	
Notes	Funding source: not reported Conflict of interest: not reported Power calculation: not reported

[NCT03185611](#)

Trial name or title	Effectiveness of Rifaximin Combined With Thiopurine on Preventing Postoperative Recurrence in Crohn's Disease
Methods	RCT, parallel design, multi-centre study, single blinded (Outcomes Assessor); Location: China
Participants	120 participants, aged 18 to 65 years Inclusion criteria: 1. Consecutive patients with Crohn's disease undergoing intestinal resection of all macroscopic diseased bowel, with an endoscopically accessible ileocolic anastomosis; 2. Enrolled patients must have one or more risk factor for the development of postoperative recurrence including penetrating disease behaviour, prior bowel resection, and active smoking. Exclusion criteria: 1. Severe co-morbidities; 2. With a stoma; 3. With malignancy; 4. Pregnancy; 5. Intolerant of thiopurine drugs; 6. With contraindication of using rifaximin or thiopurine drug
Interventions	Two arms; Arm 1: Prescribed Rifaximin (600mg, twice daily) combined with Azathioprine (2.0-2.5mg/kg/day) for 3 months after surgery, and then Azathioprine monotherapy (2.0 to 2.5 mg/kg/day) for the next 3 months and Arm 2: Prescribed Azathioprine (2.0 to 2.5 mg/kg/day) for 6 months after surgery
Outcomes	Primary: Incidence of endoscopic recurrence 6 months after surgery Secondary: Adverse effect
Starting date	June 14, 2017

Notes	

Trial name or title	Azathioprine maintenance treatment versus infliximab maintenance treatment in Crohn's disease patients in remission (Azorix trial)
Methods	
Participants	<p>Inclusion criteria:</p> <ol style="list-style-type: none"> 1. Age between 18 and 80 years 2. For at least 6 months a stable dose of combination therapy with IFX and AZA or with IFX and 6MP 3. CD in remission for at least 6 months <p>Exclusion criteria:</p> <ol style="list-style-type: none"> 1. Failed attempt to quit medication during combination therapy before 2. Abdominal abscesses, fistulas and fluid collections 3. Comorbidity or extra-intestinal complications that require infliximab treatment 4. Crohn's disease activity of the upper gastrointestinal tract that requires infliximab treatment 5. Legally incompetent patients
Interventions	<p>Two arms. Arm 1:Infliximab consisting of infusions of 5 mg/kg. Patients will receive maintenance therapy at intervals of 6 to 12 weeks</p> <p>Arm 2: Azathioprine in a dose of 2.5 mg/kg daily; 6-MP will be continued in a dose of 1.5 mg/kg daily</p>
Outcomes	<p>Primary outcome: The occurrence of relapse - defined as a disease activity with a CDAI score greater than 150 - during the 12 months follow-up period</p> <p>Secondary outcome:Mucosal healing at 12 months; Number of treatment failures after 12 months; Time to relapse; HRQOL at 12 months, measured by IBDQ</p>
Starting date	1st August 2008

DATA AND ANALYSES

Comparison 1. Azathioprine or 6-mercaptopurine versus placebo

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Clinical relapse at 12 to 36 months (subgroup by drug type)	3	408	Risk Ratio (M-H, Random, 95% CI)	0.79 [0.67, 0.92]
1.1 Azathioprine	1	81	Risk Ratio (M-H, Random, 95% CI)	0.59 [0.33, 1.08]
1.2 6-mercaptopurine	2	327	Risk Ratio (M-H, Random, 95% CI)	0.80 [0.68, 0.94]
2 Clinical relapse (subgroup by length of follow-up)	3	408	Risk Ratio (M-H, Random, 95% CI)	0.79 [0.67, 0.92]
2.1 12 months or less	1	81	Risk Ratio (M-H, Random, 95% CI)	0.59 [0.33, 1.08]
2.2 Over 12 months	2	327	Risk Ratio (M-H, Random, 95% CI)	0.80 [0.68, 0.94]
3 Endoscopic relapse at 12 to 36 months (subgroup by drug type)	2	321	Risk Ratio (M-H, Random, 95% CI)	0.85 [0.64, 1.13]
3.1 Azathioprine	1	81	Risk Ratio (M-H, Random, 95% CI)	0.70 [0.51, 0.97]
3.2 6-mercaptopurine	1	240	Risk Ratio (M-H, Random, 95% CI)	0.95 [0.81, 1.11]
4 Endoscopic relapse (subgroup by length of follow-up)	2	321	Risk Ratio (M-H, Random, 95% CI)	0.85 [0.64, 1.13]
4.1 12 months or less	1	81	Risk Ratio (M-H, Random, 95% CI)	0.70 [0.51, 0.97]
4.2 Over 12 months	1	240	Risk Ratio (M-H, Random, 95% CI)	0.95 [0.81, 1.11]
5 Adverse events at 12 to 24 months (subgroup by drug type)	2	168	Risk Ratio (M-H, Random, 95% CI)	1.36 [0.57, 3.27]
5.1 Azathioprine	1	81	Risk Ratio (M-H, Random, 95% CI)	0.77 [0.18, 3.22]
5.2 6-mercaptopurine	1	87	Risk Ratio (M-H, Random, 95% CI)	1.91 [0.64, 5.75]
6 Adverse events (subgroup by length of follow-up)	2	168	Risk Ratio (M-H, Random, 95% CI)	1.36 [0.57, 3.27]
6.1 12 months or less	1	81	Risk Ratio (M-H, Random, 95% CI)	0.77 [0.18, 3.22]
6.2 Over 12 months	1	87	Risk Ratio (M-H, Random, 95% CI)	1.91 [0.64, 5.75]
7 Serious adverse events at 24 to 36 months	2	327	Risk Ratio (M-H, Random, 95% CI)	1.78 [0.39, 8.18]
8 Withdrawal due to adverse events at 12 to 36 months (subgroup by drug type)	3	408	Risk Ratio (M-H, Random, 95% CI)	0.90 [0.63, 1.29]
8.1 Azathioprine	1	81	Risk Ratio (M-H, Random, 95% CI)	0.77 [0.18, 3.22]
8.2 6-mercaptopurine	2	327	Risk Ratio (M-H, Random, 95% CI)	1.07 [0.50, 2.27]
9 Withdrawal due to adverse events (subgroup by length of follow-up)	3	408	Risk Ratio (M-H, Random, 95% CI)	0.90 [0.63, 1.29]
9.1 12 months or less	1	81	Risk Ratio (M-H, Random, 95% CI)	0.77 [0.18, 3.22]
9.2 Over 12 months	2	327	Risk Ratio (M-H, Random, 95% CI)	1.07 [0.50, 2.27]

Comparison 2. Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Clinical relapse at 12 to 24 months (subgroup by drug type)	4	347	Risk Ratio (M-H, Random, 95% CI)	1.05 [0.89, 1.24]
1.1 Azathioprine	3	256	Risk Ratio (M-H, Random, 95% CI)	1.13 [0.94, 1.37]
1.2 6-mercaptopurine	1	91	Risk Ratio (M-H, Random, 95% CI)	0.91 [0.70, 1.18]
2 Clinical relapse (subgroup by length of follow-up)	4	347	Risk Ratio (M-H, Random, 95% CI)	1.05 [0.89, 1.24]
2.1 12 months or less	1	79	Risk Ratio (M-H, Random, 95% CI)	1.08 [0.84, 1.39]
2.2 Over 12 months	3	268	Risk Ratio (M-H, Random, 95% CI)	1.07 [0.82, 1.39]
3 Endoscopic relapse at 24 months	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
4 Radiologic relapse at 24 months	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
5 Surgical relapse at 24 months	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
6 Adverse events at 12 to 24 months (subgroup by drug type)	4	346	Risk Ratio (M-H, Random, 95% CI)	0.89 [0.74, 1.07]
6.1 Azathioprine	3	255	Risk Ratio (M-H, Random, 95% CI)	0.87 [0.70, 1.09]
6.2 6-mercaptopurine	1	91	Risk Ratio (M-H, Random, 95% CI)	1.40 [0.54, 3.62]
7 Adverse events (subgroup by length of follow-up)	4	346	Risk Ratio (M-H, Random, 95% CI)	0.89 [0.74, 1.07]
7.1 12 months or less	1	78	Risk Ratio (M-H, Random, 95% CI)	0.85 [0.70, 1.03]
7.2 Over 12 months	3	268	Risk Ratio (M-H, Random, 95% CI)	0.94 [0.64, 1.38]
8 Serious adverse events at 12 to 24 months (subgroup by drug type)	3	311	Risk Ratio (M-H, Random, 95% CI)	3.39 [1.26, 9.13]
8.1 Azathioprine	2	220	Risk Ratio (M-H, Random, 95% CI)	4.68 [0.64, 34.12]
8.2 6-mercaptopurine	1	91	Risk Ratio (M-H, Random, 95% CI)	4.69 [0.23, 95.00]
9 Serious adverse events (subgroup by length of follow-up)	3	311	Risk Ratio (M-H, Random, 95% CI)	3.39 [1.26, 9.13]
9.1 12 months or less	1	78	Risk Ratio (M-H, Random, 95% CI)	19.00 [1.15, 313.35]
9.2 Over 12 months	2	233	Risk Ratio (M-H, Random, 95% CI)	2.63 [1.12, 6.16]
10 Withdrawal due to adverse events at 12 to 24 months (subgroup by drug type)	5	425	Risk Ratio (M-H, Random, 95% CI)	2.21 [1.28, 3.81]
10.1 Azathioprine	4	334	Risk Ratio (M-H, Random, 95% CI)	2.76 [1.41, 5.40]
10.2 6-mercaptopurine	1	91	Risk Ratio (M-H, Random, 95% CI)	1.40 [0.54, 3.62]
11 Withdrawal due to adverse events (subgroup by length of follow-up)	5	425	Risk Ratio (M-H, Random, 95% CI)	2.21 [1.28, 3.81]
11.1 12 months or less	2	157	Risk Ratio (M-H, Random, 95% CI)	3.54 [0.83, 15.08]
11.2 Over 12 months	3	268	Risk Ratio (M-H, Random, 95% CI)	1.95 [1.03, 3.68]
12 HRQoL - IBDQ > 170 at 24 months	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
13 HRQoL - IBDQ at 12 months	1		Mean Difference (IV, Fixed, 95% CI)	Totals not selected

Comparison 3. Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Clinical relapse at 12 to 24 months	3	139	Risk Ratio (M-H, Random, 95% CI)	2.89 [1.50, 5.57]
2 Clinical relapse (subgroup by length of follow-up)	3	139	Risk Ratio (M-H, Random, 95% CI)	2.89 [1.50, 5.57]
2.1 12 months or less	2	106	Risk Ratio (M-H, Random, 95% CI)	2.27 [1.07, 4.82]
2.2 Over 12 months	1	33	Risk Ratio (M-H, Random, 95% CI)	6.12 [1.63, 22.97]
3 Endoscopic relapse at 12 to 24 months (subgroup by drug type)	4	157	Risk Ratio (M-H, Random, 95% CI)	3.67 [1.05, 12.81]
3.1 Azathioprine	3	138	Risk Ratio (M-H, Random, 95% CI)	3.47 [0.75, 16.03]
3.2 6-mercaptopurine	1	19	Risk Ratio (M-H, Random, 95% CI)	5.5 [0.75, 40.36]
4 Endoscopic relapse (subgroup by length of follow-up)	4	157	Risk Ratio (M-H, Random, 95% CI)	3.67 [1.05, 12.81]
4.1 12 months or less	3	124	Risk Ratio (M-H, Random, 95% CI)	2.44 [0.83, 7.18]
4.2 Over 12 months	1	33	Risk Ratio (M-H, Random, 95% CI)	10.35 [1.50, 71.32]
5 Radiologic relapse at 12 to 24 months	2		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
6 Histologic relapse at 12 months	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
7 Adverse events at 12 to 24 months	2	117	Risk Ratio (M-H, Random, 95% CI)	1.13 [0.83, 1.53]
8 Adverse events (subgroup by length of follow-up)	2	117	Risk Ratio (M-H, Random, 95% CI)	1.13 [0.83, 1.53]
8.1 12 months or less	1	84	Risk Ratio (M-H, Random, 95% CI)	1.04 [0.65, 1.66]
8.2 Over 12 months	1	33	Risk Ratio (M-H, Random, 95% CI)	1.20 [0.81, 1.78]
9 Serious adverse events at 12 months	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected
10 Withdrawal due to adverse events at 12 to 24 months	3	139	Risk Ratio (M-H, Random, 95% CI)	3.97 [0.92, 17.22]
11 Withdrawal due to adverse events (subgroup by length of follow-up)	3	141	Risk Ratio (M-H, Random, 95% CI)	4.17 [0.99, 17.47]
11.1 12 months or less	2	106	Risk Ratio (M-H, Random, 95% CI)	7.17 [1.32, 38.96]
11.2 Over 12 months	1	35	Risk Ratio (M-H, Random, 95% CI)	1.06 [0.07, 15.62]
12 HRQoL - IBDQ > 170 at 24 months	1		Risk Ratio (M-H, Fixed, 95% CI)	Totals not selected

Analysis 1.1. Comparison 1 Azathioprine or 6-mercaptopurine versus placebo, Outcome 1 Clinical relapse at 12 to 36 months (subgroup by drug type).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 1 Azathioprine or 6-mercaptopurine versus placebo

Outcome: 1 Clinical relapse at 12 to 36 months (subgroup by drug type)

Analysis 1.2. Comparison 1 Azathioprine or 6-mercaptopurine versus placebo, Outcome 2 Clinical relapse (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 1 Azathioprine or 6-mercaptopurine versus placebo

Outcome: 2 Clinical relapse (subgroup by length of follow-up)

Analysis 1.3. Comparison 1 Azathioprine or 6-mercaptopurine versus placebo, Outcome 3 Endoscopic relapse at 12 to 36 months (subgroup by drug type).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 1 Azathioprine or 6-mercaptopurine versus placebo

Outcome: 3 Endoscopic relapse at 12 to 36 months (subgroup by drug type)

Analysis 1.4. Comparison 1 Azathioprine or 6-mercaptopurine versus placebo, Outcome 4 Endoscopic relapse (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 1 Azathioprine or 6-mercaptopurine versus placebo

Outcome: 4 Endoscopic relapse (subgroup by length of follow-up)

Analysis 1.5. Comparison 1 Azathioprine or 6-mercaptopurine versus placebo, Outcome 5 Adverse events at 12 to 24 months (subgroup by drug type).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 1 Azathioprine or 6-mercaptopurine versus placebo

Outcome: 5 Adverse events at 12 to 24 months (subgroup by drug type)

Analysis 1.6. Comparison 1 Azathioprine or 6-mercaptopurine versus placebo, Outcome 6 Adverse events (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 1 Azathioprine or 6-mercaptopurine versus placebo

Outcome: 6 Adverse events (subgroup by length of follow-up)

Analysis 1.7. Comparison 1 Azathioprine or 6-mercaptopurine versus placebo, Outcome 7 Serious adverse events at 24 to 36 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 1 Azathioprine or 6-mercaptopurine versus placebo

Outcome: 7 Serious adverse events at 24 to 36 months

Analysis 1.8. Comparison 1 Azathioprine or 6-mercaptopurine versus placebo, Outcome 8 Withdrawal due to adverse events at 12 to 36 months (subgroup by drug type).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 1 Azathioprine or 6-mercaptopurine versus placebo

Outcome: 8 Withdrawal due to adverse events at 12 to 36 months (subgroup by drug type)

Analysis 1.9. Comparison 1 Azathioprine or 6-mercaptopurine versus placebo, Outcome 9 Withdrawal due to adverse events (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 1 Azathioprine or 6-mercaptopurine versus placebo

Outcome: 9 Withdrawal due to adverse events (subgroup by length of follow-up)

Analysis 2.1. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 1 Clinical relapse at 12 to 24 months (subgroup by drug type).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 1 Clinical relapse at 12 to 24 months (subgroup by drug type)

Analysis 2.2. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 2 Clinical relapse (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 2 Clinical relapse (subgroup by length of follow-up)

Analysis 2.3. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 3 Endoscopic relapse at 24 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 3 Endoscopic relapse at 24 months

Analysis 2.4. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 4 Radiologic relapse at 24 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 4 Radiologic relapse at 24 months

Analysis 2.5. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 5 Surgical relapse at 24 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 5 Surgical relapse at 24 months

Analysis 2.6. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 6 Adverse events at 12 to 24 months (subgroup by drug type).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 6 Adverse events at 12 to 24 months (subgroup by drug type)

(Continued ...)

Analysis 2.7. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 7 Adverse events (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 7 Adverse events (subgroup by length of follow-up)

(Continued . . .)

Analysis 2.8. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 8 Serious adverse events at 12 to 24 months (subgroup by drug type).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 8 Serious adverse events at 12 to 24 months (subgroup by drug type)

(Continued . . .)

Analysis 2.9. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 9 Serious adverse events (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 9 Serious adverse events (subgroup by length of follow-up)

(Continued . . .)

Analysis 2.10. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 10 Withdrawal due to adverse events at 12 to 24 months (subgroup by drug type).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 10 Withdrawal due to adverse events at 12 to 24 months (subgroup by drug type)

(Continued . . .)

Analysis 2.11. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 11 Withdrawal due to adverse events (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 11 Withdrawal due to adverse events (subgroup by length of follow-up)

(Continued . . .)

Analysis 2.12. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 12 HRQoL - IBDQ > 170 at 24 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 12 HRQoL - IBDQ > 170 at 24 months

Analysis 2.13. Comparison 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid, Outcome 13 HRQoL - IBDQ at 12 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 2 Azathioprine or 6-mercaptopurine versus 5-aminosalicylic acid

Outcome: 13 HRQoL - IBDQ at 12 months

Analysis 3.1. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 1 Clinical relapse at 12 to 24 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 1 Clinical relapse at 12 to 24 months

Analysis 3.2. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 2 Clinical relapse (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 2 Clinical relapse (subgroup by length of follow-up)

Analysis 3.3. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 3 Endoscopic relapse at 12 to 24 months (subgroup by drug type).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 3 Endoscopic relapse at 12 to 24 months (subgroup by drug type)

Analysis 3.4. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 4 Endoscopic relapse (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 4 Endoscopic relapse (subgroup by length of follow-up)

Analysis 3.5. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 5 Radiologic relapse at 12 to 24 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 5 Radiologic relapse at 12 to 24 months

Analysis 3.6. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 6 Histologic relapse at 12 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 6 Histologic relapse at 12 months

Analysis 3.7. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 7 Adverse events at 12 to 24 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 7 Adverse events at 12 to 24 months

Analysis 3.8. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 8 Adverse events (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 8 Adverse events (subgroup by length of follow-up)

Analysis 3.9. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 9 Serious adverse events at 12 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 9 Serious adverse events at 12 months

Analysis 3.10. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 10 Withdrawal due to adverse events at 12 to 24 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 10 Withdrawal due to adverse events at 12 to 24 months

Analysis 3.11. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 11 Withdrawal due to adverse events (subgroup by length of follow-up).

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 11 Withdrawal due to adverse events (subgroup by length of follow-up)

Analysis 3.12. Comparison 3 Azathioprine or 6-mercaptopurine versus anti TNF- α , Outcome 12 HRQoL - IBDQ > 170 at 24 months.

Review: Azathioprine and 6-mercaptopurine for maintenance of surgically-induced remission in Crohn's disease

Comparison: 3 Azathioprine or 6-mercaptopurine versus anti TNF- α

Outcome: 12 HRQoL - IBDQ > 170 at 24 months

ADDITIONAL TABLES

Table 1. Key definitions and outcomes

Comparison	Study ID	Time from surgery till recruitment	Site of surgery % / exclusions	Clinical relapse definition	Endoscopic / surgical/ radiologic/ histological relapse definition/
AZA & 6-MP versus Placebo					
AZA versus Placebo (12 months) both arms 750 mg/day metronidazole (3 months)	D'Haens 2008	2 weeks	Perforating disease 48 *Macroscopic evidence for CD proximally or distally to the site of resection or the presence of frank pancolitis or an ileorectal anastomosis, patients with a stoma; operation for fibrostenosis only	CDAI > 250	Rutgeerts i \geq 2
6-MP 50 mg/day versus Placebo (24 months)	Hanauer 2004	Before postoperative hospital discharge	N/A * Active perianal disease or any active disease in other segments of the intes-	Clinical recurrence grading > 2 (Hanauer)	Rutgeerts i \geq 2 Ra-diographic relapse: Radiographic recurrence grading > 2

Table 1. Key definitions and outcomes (Continued)

			tine		
6-MP 1 mg/kg/day versus Placebo (3 years)	Mowat 2016	≤ 3 months	Ileal 39; Colonic 2; Ileocolonic 59 * Need for further surgery, stricturoplasty alone, formation of a stoma	CDAI > 150 and a 100-point increase from baseline	Rutgeerts i ≥ 2 HRQOL: IBDQ scores
AZA & 6-MP vs 5-ASA					
AZA 2 mg/kg versus Mesalamine 3 mg/kg (24 months)	Ardizzone 2004	Maximum 2 weeks	Small bowel only 25. 3; Colon 5.6; Small bowel and colon 9.8; upper gastrointestinal tract 16.2 *Surgical procedures other than conservative surgery or for perianal disease only	CDAI > 200 Surgical relapse: need for another surgical procedure	n/a
6-MP 50 mg/day versus Mesalamine 3 g/day (24 months)	Hanauer 2004	Before postoperative hospital discharge	N/A * Active perianal disease or any active disease in other segments of the intestine	clinical recurrence grading > 2	Rutgeerts i ≥ 2 Radiographic relapse: radiographic recurrence grading > 2
AZA 2 mg/kg/day versus Mesalamine 4 g/day (12 months)	Reinisch 2010	6-24 months	N/A * Short bowel syndrome, an ileocolonic stoma	CDAI > 200	Rutgeerts i ≥ 2 HRQOL: IBDQ
AZA 2 mg/kg/day versus Mesalazine 3 g/day (24 months)	Savarino 2013	2-4 weeks	Ileum 49, Ileocolonic 51. * Fibrostenotic stricture, macroscopically active disease not resected at the time of surgery, and presence of a stoma	1. ≥ 2 on the clinical recurrence grading scale by Hanauer 2. CDAI > 200	Rutgeerts i ≥ 2 Radiologic relapse: ≥ 2 radiographic recurrence grading scale HRQI: IBDQ > 170
AZA & 6-MP vs anti-TNF-α					
AZA 2.5 mg versus Infliximab 5 mg/kg (12 months)	Armuzzi 2013	2-4 weeks	Not reported * Active perianal disease, presence of stoma	HBI ≥ 8	Rutgeerts' score ≥ i2

Table 1. Key definitions and outcomes (Continued)

AZA 2 mg/kg/day versus Adalimumab (24 months)	Savarino 2013	2-4 weeks	Ileum 49, Ileocolonic 51. * Fibrostenotic stricture, macroscopically active disease not resected at the time of surgery, and presence of a stoma	1. ≥ 2 on the clinical recurrence grading scale by Hanauer 2. CDAI > 200	Rutgeerts $i \geq 2$ Radiologic relapse: ≥ 2 radiographic recurrence grading scale HRQL: IBDQ > 170
AZA 2.5 mg/kg/day versus Adalimumab (52 weeks) both arms 750mg/day metronidazole (3 months)	Lopez-Sanroman 2017	2 weeks	Ileal 58, ileocolonic 41 * Postsurgical stoma, resection for short indolent stenosis, inaccessible anastomosis to endoscopy	CDAI > 200	Rutgeerts $i \geq 2$
6-MP 1.5 mg/kg/day versus Adalimumab (12 months)	Scapa 2015	< 45 days	6-MP 1.5 mg/kg/day vs Placebo (12 months)	Scapa 2015	< 45 days

AZA: azathioprine; 6-MP: 6-mercaptopurine; mg: milligram; CD: Crohn's disease; CDAI: Crohn's disease activity index; NA: not applicable; kg: kilogram; g: gram; HRQOL: health related quality of life; IBDQ: inflammatory bowel disease questionnaire; TNF: tumour necrosis factor; HBI: Harvey Bradshaw index; 5-ASA: 5-aminosalicylic acid

Table 2. Summary of interventions and outcomes

Study ID	Group 1	Group 2	Group 3	Relapse	Quality of Life	Adverse Events/ Serious adverse/ Withdrawal due to adverse events	
Ardizzone 2004	Azathioprine (2mg/kg/day)	Mesalamine (3g/day)		Clinical: 32/71 vs 35/71 Surgical: 26/71 vs 21/71	n/a	AE: 18/71 vs 27/71 SAE: 6/71 vs 15/71 Withdrawal due to AE: 6/71 vs 15/71	

Table 2. Summary of interventions and outcomes (Continued)

Armuzzi 2013	Azathioprine (2.5 mg/kg/day) Infliximab (5 mg/kg/day)	Infliximab (5 mg/kg/day)		Clinical: 2/11 vs 1/11 Endoscopic: 5/11 vs 1/11; Histologic: 9/11 vs 2/11	n/a	Withdrawal due to AE: 0/11 vs 1/11	
D'Haens 2008	Metronidazole (750 mg/day) first 3 mo + Azathioprine (100-150 mg/day)	Metronidazole (750mg/day) first 3 months + Placebo		Clinical: 11/40 vs 19/41 Endoscopic: 22/40 vs 32/41	n/a	AE: 3/40 vs 4/41 Withdrawal due to AE: 3/40 vs 4/41	
Hanauer 2004	6-Mercaptopurine (50 mg/day)	Mesalamine (3 g/day)	Placebo	Clinical: 32/47 vs 33/44 vs 35/40	n/a	AE: 9/47 vs 6/44 vs 4/40 SAE: 2/47 vs 0/44 vs 2/40 Withdrawal due to AE: 9/47 vs 6/44 vs 4/40	
Lopez-Sanroman 2017	Azathioprine (2.5 mg/kg/d) + Metronidazole (750 mg/day) first 3 mo	Adalimumab + Metronidazole (750 mg/day) first 3 mo		Clinical: 14/39 vs 7/45 Endoscopic: 23/39 vs 19/45 Radiologic: 26/39 vs 22/45	n.s. changes between groups	AE: 20/45 vs 18/39 SAE: 9/45 vs 4/39 Withdrawal due to AE: 1/39 vs 9/45	
Mowat 2016	Mercaptopurine (1 mg/kg/day)	Placebo		Clinical: 66/128 vs 70/112 Endoscopic: 90/128 vs 83/112	n.s differences	SAE: 3/128 vs 2/112 Withdrawal due to AE: 39/128 vs 41/112	
Reinisch 2010	Aza-thioprine (2.0-2.5 mg/kg/d) + Placebo mesalazine	Mesalazine (4g/d) + Placebo azathioprine		Not included	Mean IBDQ change	AE: 34/37 vs 32/41 SAE: 0/37 vs 10/41 Withdrawal due to AE: 1/37 vs 10/41	

Table 2. Summary of interventions and outcomes (Continued)

Savarino 2013	Adalimumab (160-80 mg 0-2 weeks and 40 mg/week thereafter)	Azathioprine (2 mg/kg/day)	Mesalamine (3 g/day)	Clinical by Hanauer score: 2/16 vs 12/17 vs 9/18 Clinical by CDAI: 1/16 vs 12/17 vs 9/18 Endoscopic: 1/16 vs 11/17 vs 15/18 Radiologic: 1/16 vs 13/17 vs 15/18	HRQOL (IBDQ>170): 14/16 vs 2/17 vs 3/18	AE: 11/16 vs 14/17 vs 14/18 Withdrawal due to AE: 0/16 vs 1/17 vs 1/18	
Scapa 2015	6-mercaptopurine (1.5 mg/kg/day)	Adalimumab (160-80-40 mg/2 week intervals)		Endoscopic: 4/8 vs 1/11	n/a	n/a	

mg: milligram; kg: kilogram; g: gram; CDAI: Crohn's disease activity index; NA: not applicable; AE: adverse events; SAE: serious adverse events; HRQOL: health related quality of life; IBDQ: inflammatory bowel disease questionnaire; ns: not significant

WHAT’S NEW

Date	Event	Description
31 July 2019	New search has been performed	New search and new studies added
31 July 2019	New citation required and conclusions have changed	Updated review with new authors

CONTRIBUTIONS OF AUTHORS

Morris Gordon provided methodological expertise and performed screening of abstracts and titles, screening of full-text articles and was involved with adjudication of GRADE analysis, manuscript preparation, critical revision of the manuscript, and approval of the final manuscript.

Anthony K Akobeng provided methodological expertise and was involved with checking the data analyses, data interpretation, manuscript preparation, critical revision for the manuscript, and approval of the final manuscript.

Zipporah Iheozor-Ejiofor performed adjudication in the screening and data extraction phases, data extraction, communication with primary study authors, risk of bias assessments, GRADE analysis, manuscript preparation, critical revision for the manuscript and approval of the final manuscript.

Teuta Gjuladin-Hellon performed data extraction, risk of bias assessments, statistical analyses, data interpretation, manuscript preparation, GRADE analysis, critical revision for the manuscript and approval of the final manuscript.

DECLARATIONS OF INTEREST

Teuta Gjuladin-Hellon: None known.

Zipporah Iheozor-Ejiofor: None known.

Morris Gordon: Received travel fees to attend international scientific and training meeting such as DDW, Advances in IBD, ESPGHAN, BSPGHAN and Cochrane focused international events from companies including: Abbott, Nutricia, Biogaia, Ferring, Allergan, and Tillots.

Anthony K Akobeng: None known.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

The scope of this review was expanded to include:

- Trials which compare AZA and 6-MP with no treatment were not included in the previous version of this review. If such trials become available in future updates, we intend to analyse them separately from the placebo trials
- Inclusion criteria is limited to studies with minimum of 3 months of treatment versus 6 months in the previous review.
- Endoscopic recurrence was a primary outcome in the previous version of the review, however, we decided to report it as a secondary outcome in this review to ensure consistency across the Cochrane IBD group portfolio.
- We also reported adverse event data as a composite outcome not individually as proposed in [Gordon 2014](#) to ensure consistency across the Cochrane IBD group portfolio
- Radiologic, surgical, histologic relapse and health related quality of life are additional outcomes which were only included in this version of the review to ensure consistency across the Cochrane IBD group portfolio.
- We included abstracts in this review.
- For the previously published version of this review we contacted leaders in the field and drug manufacturers to identify additional studies. We did not do this for the updated review.

INDEX TERMS

Medical Subject Headings (MeSH)

Adalimumab; Anti-Inflammatory Agents, Non-Steroidal [therapeutic use]; Antibodies, Monoclonal [therapeutic use]; Antibodies, Monoclonal, Humanized [therapeutic use]; Azathioprine [*therapeutic use]; Crohn Disease [*drug therapy; prevention & control; surgery]; Immunosuppressive Agents [*therapeutic use]; Infliximab; Maintenance Chemotherapy [*methods]; Mercaptopurine [*therapeutic use]; Mesalamine [therapeutic use]; Randomized Controlled Trials as Topic; Remission Induction [methods]; Secondary Prevention
